PB07 — The source-viscosity-to-cutoff-clock morphism is absent from the retained response Locator. A0656, LF2866, explicitly names a viscosity-one stage. A0706, LF3571–3577, retains target viscosity r_c ; LF3611–3627 embeds by $\tau = t$ with unchanged spatial coordinates. **Proved or displayed.** The target proper clock and $\nu_{\text{proper}} = c\sqrt{r_c}$. **Missing.** The actual equation-preserving parameter dictionary from the source viscosity to this target and the induced endpoint/norm factors. **Finished here.** VISCOSITY_MAP.md proves the invertible map $b = r_c/\nu_s$, $t = b\tau$, $v = bu$, $P = b^2 p$, $f^{\text{cut}} = b^2 f$, its domain, endpoint image, kinetic and dissipation factors, and Brown-York coefficient. **Scope.** The direct unchanged-clock identification only intertwines the displayed equations when $r_c = \nu_s$. This is a repair of a missing parameter morphism, not an obstruction to the fluid/gravity program. The linked full note may contain additional dictionary data; this bounded audit makes no claim about unread artifact contents.

PB08 — The boundary-force construction is exact on each preterminal interval and needs the actual endpoint calculation Locator. A0706, LF3660–3697; “does not assert an uncomputed smooth terminal metric”. **Objects.** $A_t = -(\Phi_t^{-1})^* \int_0^t \Phi_s^* f_s ds$, $h_{00} = -2v^j A_j$, the actual source flow, and the forcing equation. **Proved.** The coordinate force identity, retaining the transport and one-form derivative terms. **Missing.** Terminal control of $D\Phi_t^{-T} \int_0^t D\Phi_s^T f_s \circ \Phi_s ds$, its spatial/time derivatives, and the resulting metric-source coefficients on the actual NS field. **Finished here.** CALCULATIONS.md §5 expands the exact derivative factors and constructs an explicit smooth preterminal forced incompressible NS comparison with terminal-flat force and divergent coefficients. **Scope.** The comparison is not finite-energy or compactly supported, so it does not decide the manuscript’s profile. It proves only that the general smooth-force inference is invalid. **Next derivation.** Calculate these factors for the actual retained field, retaining all support and logarithmic corrections, and feed them into the chosen gravitational construction.

PB09 — The higher-derivative ratio is a real obstruction to uniform truncation, not to a full endpoint Locator. A0706, LF3805–3831; “which gravitational approximation has stopped controlling the answer”. **Objects.** Leading $-r_c \Delta v_i$, actual correction $-\frac{3}{2} r_c^2 \Delta^2 v_i$, and the source pulse wavelengths with their retained support/logarithmic factors. **Proved.** For a fixed Fourier component, the magnitude ratio is exactly $\frac{3}{2} r_c |k|^2$; this grows on decreasing source wavelengths. **Missing.** The complete higher-order/source-dependent cancellation or domination calculation, controlled re-summation/full Einstein solution, and endpoint observables. **Scope.** A single unbounded relative coefficient rules out asserting uniform control from the displayed finite derivative truncation. It does not establish nonexistence of an exact bulk solution or settle its curvature. **Next derivation.** Use the full retained correction equation and actual source pulses; calculate a remainder bound or solve

the relevant bulk equations with the original forcing. The exact clock morphism in PB07 does not remove this ratio.

PB10 — Partial trace proves only nonuniqueness from local histories; stronger joint data are explicit **Locator.** A0706, LF3835–3901; “The map from the joint state to local stress data is demonstrably many-to-one”. **Objects.** $m(\rho) = (\text{Tr}_R \rho, \text{Tr}_L \rho)$, TFD density, product Gibbs density, cross-energy covariance, and local drives. **Proved.** Identical marginals and identical one-sided driven histories coexist with different cross-energy covariance. **Missing.** A selected joint state and joint evolution for the actual source; a construction of geometry from those data. **Finished here.** CALCULATIONS.md §3 exhibits the entire thermofield phase family with the same marginals and the same cross-energy covariance, and gives explicit bounded cross observables recovering its relative phases. **Scope.** The obstruction reaches reconstruction from one-sided data alone. It does not establish unrelatedness of NS and entanglement, and it does not prevent reconstruction after adding sufficient joint observables. **Next derivation.** Calculate the actual cross-observable state and its dynamical relation to the source singular profile rather than treating local stress as a complete joint-state invariant.

PB11 — BC prime occupations and modular clocks match, but the global trace-class boundary must be retained **Locator.** A0706, LF3903–3972; “A spatial field net and its stress tensor are additional physical data”. **Objects.** $\ell^2(\mathbb{N})$, prime bosonic Fock occupations, $E_* \log n$, $\omega_p = E_* \log p/\hbar$, the doubled thermal vector, and the exact coefficient match. **Proved or displayed.** The occupation bijection and Hamiltonian dictionary; partition function stated in its trace-class range. **Missing.** Operator domains, the simultaneous global normalization boundary after imposing the Rindler temperature match, and the spatial/local stress realization. **Finished here.** CALCULATIONS.md §4 proves the full unitary operator/domain equality, prime product convergence, energy moments, modular sign/time map, and the exact global range $\beta E_* > 1$, equivalently $0 < a < 2\pi c E_*/\hbar$ for this correspondence. **Scope.** Failure of this particular global Gibbs normalization does not establish absence of all KMS states or a physical cooling singularity. **Next derivation.** Construct the relevant field net and full arithmetic observable correspondence on its actual state domain; retain the semigroup and multiplicities of any BCM extension instead of replacing them by the elementary ideal model.

PB12 — Equilibrium data do not determine cooling dynamics **Locator.** A0706, LF3974–3980; $\dot{n} = -\Gamma(n - n_\beta)$. **Proved.** Every $\Gamma > 0$ gives the same equilibrium occupation but a different relaxation time: direct solution is $n(t) = n_\beta + (n(0) - n_\beta)e^{-\Gamma t}$. **Missing.** A source-selected dynamical generator, coupling, and energy exchange for the proposed arithmetic physical system. **Scope.** This excludes inferring a cooling deadline from KMS populations alone, not constructing a cooling model from additional dynamics. **Next derivation.** Specify and calculate the actual generator transported by the physical/arithmetic map; pulse choices in a fixed scattering experiment do not alter the underlying zeta zeros.

PB13 — The Schwarzian diagonal identity is a local bridge; the full arithmetic kernel has not been realized **Locator.** A0706, LF3982–4058; “Identifying the full arithmetic kernel with a particular spacetime ray map remains a separate construction”. **Objects.** The exact diagonal kernel subtraction, $\{F, u\}$, central charge c_{CFT} , the null time coordinates, power $-\hbar c_{\text{CFT}}\{F, u\}/(24\pi)$, and entropy $-c_{\text{CFT}} \log F'/12$. **Proved or displayed.** The local diagonal identity and the direct entropy/flux/horizon-exponential derivative calculations. **Missing.** A full arithmetic kernel-to-ray-map morphism, including off-diagonal equality, orientation $F' > 0$, global state/boundary conditions, and transport of the arithmetic action into physical evolution. **Scope.** Sharing a local invariant neither supplies the full kernel identity nor proves incompatibility. **Next derivation.** Work on the

actual retained arithmetic kernel and solve/test the full pullback equation with the original variables and boundary data. This has not yet become a proof about the later theta source.

PB14 — No retained physical obstruction reaches A_{τ}/K_{τ} Locator. Entire assigned range, especially A0706's final LF4068–4074. **Evidence.** The range contains modular-surface scattering, BC occupation dynamics, and physical constructions, but it does not define or calculate the later $A_{\tau} = R\Gamma(P, -)$, K_{τ} , their restriction/homotopy-fibre maps, or the original theta action. **Scope.** None of the demonstrated many-to-one maps, finite-truncation limits, or trace-class boundaries proves failure of the split-base/privileged-tau program. **Integration.** Preserve the exact scattering multiplicities, units, force-map caution, and state/action questions as context. The main redo prompt must still resume the actual later A_{τ} , K_{τ} , and theta calculations, with the parent's later-turn locators. Replacing that work with the physical examples in this range would repeat the earlier scope substitution.

226.1.3 Priority for integration

1. Preserve A0706's completed maps and its correctly scoped limitations; do not label the entire physical response an abandonment.
2. Carry the exact multiplicities, operator domains, trace-class boundary, phase-sensitive joint observables, and viscosity/clock map from the new proof files into the relevant passage audit.
3. Mark the actual forced gravitational endpoint, arithmetic local-net/ray-map realization, and full packet estimates as calculations not completed in this retained range. These are concrete original-object continuations, not substitute assumptions.
4. Keep this physical precursor secondary to the current original theta/split-base continuation. This lane supplies no blanket program-failure verdict and no general ER=EPR theorem.

227 Formation of the original base: U0016–U0028

228 Formation of the original tau-base program: passage audit U0016–U0028

This audit records calculations and their scope, without judging motives. It reads the entire assigned transcript segment and the complete primary Tau_Base note and canonical source route. Six substantive answers and sixteen progress nodes cover thirteen user turns. The primary Tau_Base construction is a later successor: it determines the continuation available now, not what an earlier answer could already have read.

228.1 Coverage and source pins

- output/tau_fl_transcript_audit_2026-09-13/sources/audit_segment_U0016_U0028.md — 199,384 bytes; SHA-256 9705e32233d967f4abc6d522d40cfddc20a9f94c057d47410b37a3ee9e065298.
- output/split_zero_rh_tandem_2026-09-12/sources/Tau_Base_Cohomology_2026-09-12/NOTE.md — 25,512 bytes; SHA-256 d03e71ad18f187bd89880cb8ca6fc9c5d6f260b3de8e8e5702c27db97e7b63c3.
- work/fl_geometry_current_source_route_20260913.md — 15,362 bytes; SHA-256 a8cdd18817a2c3596778c60a04ef9d76125a03ae5404759835a2bc2b18fa4c74.

All 198,330 decoded source characters (198,330 after CRLF-to-LF conversion) were read through the last A0963 node. The contiguous reading windows and all node IDs are retained in AUDIT.json. Exact user turns are separately copied to SEGMENT_USER_INPUTS_VERBATIM.md.

Historical cited attachments and test counts are not independently verified by this lane. A0952/A0961 cite Deligne witnesses; this audit assesses what those transcript passages calculate and claim, while the root task owns independent Deligne/purity verification. U0028 remains active at the segment boundary.

228.2 Status of every user turn

Complete table entries (13 rows).

Entry 1.

User turn / node: U0016 / 7d76e278-ae0c-43db-ab75-81ea7405723a

Response nodes: A0707, A0720, A0751, A0756

Classification and evidence: **advanced-partial; universal transfer unfinished.** Full sequential reconstruction, exact ideal/character/Mellin maps and genuine bounded obstructions are delivered. §9 assumes the decisive universal transfer/decay. U0016 did request a conditional sketch component, so that component is valid but not completion of the requested full mapping.

Entry 2.

User turn / node: U0017 / 9dd06d78-abdb-4213-a643-73780d99ad1f

Response nodes: A0758

Classification and evidence: **superseded by further user steering.** Only a progress acknowledgment follows before U0018. Its correction—one support beneath distinct origins—remains active and must not be dropped.

Entry 3.**User turn / node:** U0018 / a4f2753d-2aa4-4c11-b394-3b77c1640c80**Response nodes:** A0781, A0788

Classification and evidence: **advanced side and all-degree algebra; main transfer unfinished.** The all-n holonomy construction and specifically requested ES/Jordan integration are substantive. The answer explicitly lacks identification of its chosen H with actual arithmetic zeros; U0019 repeats the main task.

Entry 4.**User turn / node:** U0019 / 844aed0c-72f8-4ac2-b351-5ad9ef346c7a**Response nodes:** A0790

Classification and evidence: **interrupted by explicit source-reading prerequisite.** A0790 states an intent to isolate the central implication; U0020 immediately requires reading the split-zero work. No substantive calculation answers U0019 in that interval.

Entry 5.**User turn / node:** U0020 / b3ff5366-d7c7-46ec-9f49-951d2f29177f**Response nodes:** A0796, A0805

Classification and evidence: **source-reading progress; scope widened by U0021.** A0805 reports reading 956 lines of globalization_note.tex and one localization theorem. This audit does not independently verify the historical reading claim. U0021 requires additional current GitHub material.

Entry 6.**User turn / node:** U0021 / 1f65ae67-a886-4ef1-9e54-082d7c928fe4**Response nodes:** A0812, A0837, A0844

Classification and evidence: **source repairs and typed maps advanced; integration unfinished.** A0844 explicitly repairs repeated-adjunction, bare- C and all-observer substitutions, giving exact replacement maps. The requested original cohomological argument is still not executed, leading to U0022/U0023.

Entry 7.**User turn / node:** U0022 / b48b70f3-9b82-48fc-b7b9-d3e6fd428c42**Response nodes:** A0862

Classification and evidence: **advanced original-object calculation; weight inference still uncalculated.** The ideal absorption, infinite norm, exact-kernel quotient and all-character weight calculation are real results. Their scope does not prove purity, and the response ends at a quoted positivity criterion.

Entry 8.**User turn / node:** U0023 / c1f5c457-5da2-439d-b133-0a4b032008ed**Response nodes:** Merged into subsequent steering

Classification and evidence: **merged into U0024; substantive response delayed.** The user makes the Deligne-at-tau construction explicit and requires reintegration. U0024 immediately states two routes; A0863 responds to the combined request. Later A0952/A0961 execute only part of that task.

Entry 9.**User turn / node:** U0024 / 65b8bdef-be04-4ac6-a7f1-9bb25a8f74f4**Response nodes:** A0863

Classification and evidence: **progress then source provenance restart.** The two routes are acknowledged. U0025 challenges Deligne reading and U0026 restarts the prompt; A0952/A0961

later give source comparison and finite coefficient/NS calculations but not arithmetic purity.

Entry 10.

User turn / node: U0025 / bd3fe5a5-4f4c-4f92-ae76-5fc2f58512d1

Response nodes: Merged into subsequent steering

Classification and evidence: **source claim challenged; later retracted.** U0025 is followed by U0026 before an assistant node. A0877 and A0952 explicitly retract the unestablished reading claim; this is source-provenance evidence, not a motive finding.

Entry 11.

User turn / node: U0026 / 0cda31d8-8a8d-428c-b551-77999e854978

Response nodes: A0877

Classification and evidence: **restart accepted; method refined by U0027.** A0877 promises to locate the actual attachment and use its precise theorems. U0027 then requires TeX-only access.

Entry 12.

User turn / node: U0027 / b48fac36-14fb-4a9b-a6fe-7d6fe8b94886

Response nodes: A0882, A0934, A0937, A0952, A0961

Classification and evidence: **source route repaired; mixed-support calculations advanced; arithmetic transfer unfinished.** A0952 reports scan checks despite TeX-only instruction; A0961 explicitly uses historical TeX witnesses and preserves discrepancies. Mixed-double localization/Frobenius and arbitrary monodromy blocks advance the algebra. The finite H_0 spectrum is not linked to original theta H_1 .

Entry 13.

User turn / node: U0028 / 9d5e82ea-d670-4145-b5d3-c22d8948133e

Response nodes: A0963

Classification and evidence: **active at assigned segment boundary.** Only a progress node is included after U0028. The response continues in the next segment, so no session-wide abandonment conclusion is drawn here.

228.3 Passage-by-passage findings

Priorities: 0 = essential original-program continuation; 1 = integrate or preserve exact scope; 2 = useful bounded source result. A finding that a result is limited is not a claim that the program fails. Each cited line is a one-based line of the retained segment.

228.3.1 BF01 — A0756 §§2.2–3.3

User U0016 (7d76e278-ae0c-43db-ab75-81ea7405723a); assistant A0756 (7feaa63b-bf8a-46d2-bffc-4ab530615f9d), chain 1444; passage line 341. Priority 1.

The finite-norm ideal correspondence is multiplicative:

Status: advanced; retain exact arithmetic maps.

Requested calculation. Recover the Dedekind system and all character sectors after adjoining the common split support; map the complete arithmetic picture.

Original objects and maps. $S=G(O_K)$, $e=0_R$, $I_J=JU\{\tau\}$, p_R , π_J , $N(I_J)=N(J)$; the ideal-basis unitary V , inertia projectors E_I , ramification-complete group-algebra Euler product.

What was actually proved. The answer gives exact norm/ideal multiplication, intertwines the log-norm Hamiltonians including their domains, gives finite character Fourier inversion, Mellin

transform $\Gamma(s)L(s,\chi)$, and repairs omitted ramified local factors. The $p=2$ factor for $Q(i)$ remains explicit.

What remained uncalculated. Those maps do not yet place the character spectral quotient in a cohomology over the absolute base, or calculate an arithmetic weight bound. This is an incomplete larger task, not an error in the retained ideal calculation.

Exact obstruction scope. No obstruction to the original program is established by arithmetic preservation; these maps are usable inputs.

Concrete surviving derivation. Attach the preserved square $G(Z) \rightarrow G(C)$, p_Z and p_C to the actual tau-base structural map and theta complex, as the later Tau_Base (2)–(8), (14), (19) do. Preserve inertia and omitted-prime data for any character generalization.

228.3.2 BF02 — A0756 §4; corrected by A0844 §1

User U0016 (7d76e278-ae0c-43db-ab75-81ea7405723a); assistant A0756 (7feaa63b-bf8a-46d2-bffc-4ab530615f9d), chain 1444; passage line 743. Priority 1.

The support-chain operations are

Status: scope substitution, explicitly repaired later.

Requested calculation. Relate one split support to the full family of distinct coordinate origins, higher nullity operations, winding and characters.

Original objects and maps. The answer uses $G_{\{C_n\}}(R[G])$, chain support max/min, and $c_n(a,j)=(a,\min(j,n-1))$. The later source correction retains interlevel maps $i_n:L_n \rightarrow L_{\{n+1\}}$ and $\text{Orig}_i(y)=i^{\{-1\}}(y)$.

What was actually proved. It proves amplitude preservation for the displayed support-chain collapse. That result is about that operation and its specified carrier; it cannot identify every origin-and-operation raise with iteration of zero adjunction.

What remained uncalculated. The actual interlevel nullity operation and its typed comparison with cyclic/character constructions were not computed. A0844 explicitly acknowledges the substitution, and U0022 clarifies that repeated realizations of the same bottom support and higher nullity operations must both remain.

Exact obstruction scope. The collapse result does not reach the full origin ladder. Equal empty origin fibres do not identify their domain points or higher operations.

Concrete surviving derivation. Retain fixed scalar $G(R)$, the full interlevel maps and their origin fibres. In the current tau model keep all masks $A \subseteq \{+,-\}$, the original T_A and their transports; compute any higher operation on those diagrams rather than replace it by c_n .

Later repair or steering: A0844 §§1–3; U0022.

228.3.3 BF03 — A0756 §4.1; corrected by A0844 §4

User U0016 (7d76e278-ae0c-43db-ab75-81ea7405723a); assistant A0756 (7feaa63b-bf8a-46d2-bffc-4ab530615f9d), chain 1444; passage line 823. Priority 1.

Complex-valued observations necessarily forget the extra zero

Status: overbroad heading; precise theorem retained and scope repaired.

Requested calculation. Carry the added supported zero into the arithmetic and operator geometry without erasing it by an inappropriate observation.

Original objects and maps. Additive unital semiring maps $G(R) \rightarrow B$ with B a ring factor through p_R ; multiplicative representations of the pointed monoid instead factor through the contracted monoid algebra.

What was actually proved. The displayed factorization theorem is correct for additive semiring maps into rings. A0844 provides the inverse of the contracted-monoid decomposition and $T(n) = \text{diag}(1, n)$, $T(\tau) = 0$, which retains $T(e) = \text{diag}(1, 0)$.

What remained uncalculated. The heading and associated interpretation exceeded the theorem type; no all-observer vanishing was proved. The central idempotent representation was initially left outside the purported complete map.

Exact obstruction scope. The ring-reflection theorem obstructs support detection only for its stated additive maps. It does not kill the multiplicative linearization or the supported cohomology fibres.

Concrete surviving derivation. Use both p_R and χ_R and keep their types. For current Q and its dual, retain supported zero functionals at every label and the actual precomposition arrows of Tau_Base (31), (43); do not infer τ from a zero complex value.

Later repair or steering: A0844 §4.

228.3.4 BF04 — A0756 §§5.1–5.4

User U0016 (7d76e278 - ae0c - 43db - ab75 - 81ea7405723a); assistant A0756 (7feaa63b - bf8a - 46d2 - bff c - 4ab530615f9d), chain 1444; passage line 934. Priority 2.

This is the concrete content of the winding/character connection.

Status: advanced; finite observation scope subsequently enlarged.

Requested calculation. Count full integer winding and map it to arithmetic holonomies, rather than treating a return of phase as loss of all winding information.

Original objects and maps. $Z \rightarrow G$, $n \mapsto \text{Frob}_p^n$, followed by χ ; the exponential covering and lifted angle; the K4 quartet coefficients $c_{\{++\}} = 2, c_{\{+-\}} = 0, c_{\{-+\}} = 4(\beta - 1/2), c_{\{-\}} = 4i\gamma$.

What was actually proved. The displayed maps retain the prime-orbit character value $\chi(\text{Frob}_p)^n$ and recover the actual real displacement from the quartet. The exponential cover of $C^\times$ has no fibre over zero, precisely for that cover.

What remained uncalculated. The requested fixed-origin full integer-action realization was not yet built in this answer. A0788 later builds it on a lifted angular space and Jordan tangent data, but still does not identify the chosen action with the actual arithmetic spectral action.

Exact obstruction scope. The empty fibre of $\exp$ over zero is a property of that particular covering. It is not an obstruction to an origin blow-up, an action groupoid at a fixed origin, or the original support base.

Concrete surviving derivation. Keep the full-turn $T_n(H)$ representation before finite character observation, then instantiate H by the original arithmetic U_a on a finite full jet packet and prove the resulting determinant/trace maps with all nilpotents.

Later repair or steering: A0788 §§1–4.

228.3.5 BF05 — A0756 §§6.2–7.2

User U0016 (7d76e278 - ae0c - 43db - ab75 - 81ea7405723a); assistant A0756 (7feaa63b - bf8a - 46d2 - bff c - 4ab530615f9d), chain 1444; passage line 1184. Priority 2.

smooth bulk extension exists for every

Status: legitimate calculated obstruction, with limited scope.

Requested calculation. Test whether a coherent higher-dimensional cancellation forces the real arithmetic period defect to vanish.

Original objects and maps. $\alpha_a = d\Phi + a d\ell$ on the circle of length L ; disk extension $(aL/2\pi)(X dY - Y dX)$; paired holonomy $\text{diag}(e^{-aL}, e^{aL})$; hyperbolic anomaly envelope $A \oplus \hat{A}$.

What was actually proved. The disk curvature integral equals aL . Flat extension of the specified meridional period forces $a=0$, but smooth curved extension exists for every a . A determinant-one pair preserves an indefinite pairing at arbitrary a ; its positive invariant form would force $a=0$. The finite hyperbolic completion is independent of the spectral zero.

What remained uncalculated. No map from the actual arithmetic theta source to the flat extension or positive form was constructed. Universal abstract cancellation alone does not supply it.

Exact obstruction scope. These are exact counterexamples to the stated implication from mere smooth completion, determinant cancellation, or an abstract finite envelope. They do not disprove a more constrained arithmetic construction over τ .

Concrete surviving derivation. Compute the actual arithmetic residue/trace pairing and its analytic source, preserving the raw orientation, moment twist and boundary terms. Use Tau_Base (38)–(45) rather than declaring an arbitrary completion to be its duality.

228.3.6 BF06 — A0756 §8

User U0016 (7d76e278-ae0c-43db-ab75-81ea7405723a); assistant A0756 (7feaa63b-bf8a-46d2-bffc-4ab530615f9d), chain 1444; passage line 1411. Priority 2.

Smooth flatness does not supply that map by itself.

Status: exact regularity distinction; transfer unfinished.

Requested calculation. Map the NS all-order residual cancellation into an arithmetic analytic identity while preserving the original singular velocity and profiles.

Original objects and maps. The explicit approach map $\beta(q, X, \eta, \theta)$, its $q^{-1/2-h}$ velocity factor, residual flatness, and the comparison germ $\exp(-1/q^2)$.

What was actually proved. The answer retains the unbounded velocity factor and identifies the weighted profile as a different observable. The flat smooth example proves that all derivatives vanishing at an endpoint do not imply the holomorphic identity theorem without a function-space transfer.

What remained uncalculated. The actual map on profiles, pressure corrections, moment conditions and residuals into the arithmetic Schwartz/Mellin spaces is not calculated.

Exact obstruction scope. Only a direct inference from smooth flatness to holomorphic vanishing is blocked. The evidence does not rule out a new controlled transformation.

Concrete surviving derivation. If this historical route is resumed, specify and calculate the map from the original NS correction histories into the original V and B seminorms, including every q -dependent weight and endpoint term. The root task now prioritizes the original theta cohomology route.

228.3.7 BF07 — A0756 §§9–9.2

User U0016 (7d76e278-ae0c-43db-ab75-81ea7405723a); assistant A0756 (7feaa63b-bf8a-46d2-bffc-4ab530615f9d), chain 1444; passage line 1451. Priority 0.

Suppose a construction assigns, to every

Status: valid conditional sketch component; requested construction interrupted.

Requested calculation. First reconstruct the whole proof sketch, then actually map its stages and prove the proposed transfer for all arithmetic sectors.

Original objects and maps. Actual zeros (χ, ρ) , $a_{\{\chi, \rho\}} = \text{Re} \rho - 1/2$, circles of fixed positive $L_{\{\chi, \rho\}}$, $\alpha_{\{j+1\}} - \alpha_j = d\varphi_j$, and an assumed L1 decay of α_j .

What was actually proved. The period-preservation argument is correct: $|a|L$ is bounded by the assumed L1 norm, hence vanishes when that norm tends to zero. U0016 explicitly asked for a sketch of what would follow if all steps were mapped, so this is responsive to that portion of the request.

What remained uncalculated. The transfer $T_{\{\chi, \rho\}}$ from actual NS correction histories, universal coverage of actual zeros, and the required decay are all introduced as assumptions. They are the substantive missing calculation, not conclusions of the theorem.

Exact obstruction scope. No obstruction is proved against the complete arithmetic program. The theorem only shows what its added hypotheses would imply; it cannot be counted as completion of those hypotheses.

Concrete surviving derivation. At the current successor, resume the actually constructed $A_{\tau}(T)$, $K_{\tau}(L1)$, $Q \rightarrow A_Z$ and dual injection. Derive an actual bound on the original theta source instead of replacing it with period decay or a positivity assumption.

228.3.8 BF08 — A0756 §10.1

User U0016 (7d76e278-ae0c-43db-ab75-81ea7405723a); assistant A0756 (7feaa63b-bf8a-46d2-bffc-4ab530615f9d), chain 1444; passage line 1654. Priority 1.

This is **not** a counterexample to GRH:

Status: legitimate bounded model test; no broad program verdict.

Requested calculation. Determine what original arithmetic rigidity follows from support, symmetry and abstract anomaly cancellation.

Original objects and maps. $P_{a,b}(s) = ((s - 1/2 - a)^2 + b^2)((s - 1/2 + a)^2 + b^2)$, $0 < a < 1/2$, $b > 0$, with the original four roots and symmetries.

What was actually proved. The polynomial has the two indicated reflection symmetries and four off-line roots. It can be assigned the general support labels and abstract envelope used in the answer. This disproves only an implication based solely on that common structure.

What remained uncalculated. No morphism identifying this polynomial family with the original arithmetic theta image, its gamma factor, trace formula or adjoint was supplied.

Exact obstruction scope. The answer expressly limits the example to non-arithmetic amplitudes. Preserve that limitation: it cannot establish failure of the tau-base program or replace its arithmetic function.

Concrete surviving derivation. Retain $g=2\xi$, the actual Θ , exact Mellin image, and A_{τ}/K_{τ} . Any subsequent surrogate bound must be transferred through a proved map before its failure is attributed to the original construction.

228.3.9 BF09 — A0788 §§2,6

User U0018 (a4f2753d-2aa4-4c11-b394-3b77c1640c80); assistant A0788 (c65ef26a-1cb7-418f-ba78-f620261edde9), chain 1521; passage line 1937. Priority 1.

All levels compose explicitly

Status: genuine all-degree advance; arithmetic instantiation incomplete.

Requested calculation. Give the full n -level cyclic/holonomy ladder, not merely its second or third example, and map its Mellin and arithmetic operations.

Original objects and maps. $T_n(H)(v_0, \dots, v_{n-1}) = (Hv_{n-1}, v_0, \dots, v_{n-2})$; $P_{\{m,n\}}(e_a \otimes e_b \otimes v) = e_{\{a+mb\}} \otimes v$; $\nu_{\{H,Q\}} = \sum a_k \delta_{\{Q^k\}}$.

What was actually proved. The answer proves $T_n(H)^n = \text{diag}(H)$, determinant $\det(I - zT_n(H)) = \det(I - z^n H)$, trace vanishing unless n divides the power, and the all-degree composition law. The pushforward $t \mapsto t^n$ gives spectral dilation with the displayed Mellin factor $1/n$ for functions. It also retains inertia invariants and nonabelian multiplicities.

What remained uncalculated. The chosen H in the main example is not derived from the actual arithmetic zero cohomology. The local finite permutation determinant and global spectral zero packet have not been joined by a map.

Exact obstruction scope. This is substantial completion of an all-degree algebra subtask; it does not by itself furnish the global GRH-sensitive invariant requested repeatedly.

Concrete surviving derivation. Apply the same proved T_n construction to $U_a|A_Z = a^\rho \exp(\log(a)N_\rho)$ on the actual full jet quotient, and compare its trace/determinant to the arithmetic theta morphism. Keep n , every multiplicity, all powers of N and the original a .

228.3.10 BF10 — A0788 §§3–5,8

User U0018 (a4f2753d - 2aa4 - 4c11 - b394 - 3b77c1640c80); assistant A0788 (c65ef26a - 1cb7 - 418f - ba78 - f620261edde9), chain 1521; passage line 2690. Priority 1.

It does not identify the chosen Jordan holonomy with a particular arithmetic zero

Status: authorized side construction advanced; main transfer left unfinished.

Requested calculation. Map the three-coordinate/Jordan/ES component as part of the entire arithmetic program; U0018 also explicitly requested ES repository integration.

Original objects and maps. $J = H_3(O)$, marked frame, Cayley–Dickson coordinates, $H = G_{\{(3+4i)/5\}C}$, $T_n(H)$, exact defect $\Delta(q) = -1$ and rational ES chart.

What was actually proved. The response gives an all-integer faithful automorphism construction, an ordered-frame tangent map, retained cubic coupling $2\text{Re}((xy)z)$, and the reversible non-diagonal ES chart preserving $\Delta = -1$. It expressly admits the missing arithmetic-zero identification.

What remained uncalculated. The construction does not calculate the requested universal interlevel arithmetic realization or show that this specific holonomy is the one on the original zeta zero space. U0019 repeats the still-open initial task; A0844 later retracts counting these examples as execution of the whole program.

Exact obstruction scope. No failure of the full program follows. The example shows that a fixed projected origin can retain winding; that success is compatible with the missing arithmetic identification.

Concrete surviving derivation. Keep the proved ES and Jordan maps as their own results. Resume the common-support arithmetic cohomology and derive its actual action, rather than selecting another illustrative holonomy.

Later repair or steering: A0844 §§1,7.

228.3.11 BF11 — A0844 §§1–3,7

User U0021 (1f65ae67 - a886 - 4ef1 - 9e54 - 082d7c928fe4); assistant A0844 (2aeb23d1 - e3be - 4204 - 9bc2 - 3abe87a3cbcd), chain 1712; passage line 2807. Priority 1.

My error was to substitute

Status: source repair completed; program continuation still absent.

Requested calculation. Read the actual current globalization/nullity sources, correct previous mistakes, and integrate those corrections into the original task.

Original objects and maps. Free zero-adjunction $Z \dashv U$ over a fixed zero-forgotten input; common scalar $S0=G(R)$; $A_d=R[x_1, \dots, x_d]$; $j_d^*: A_{d+1} \rightarrow A_d$ and ε_d .

What was actually proved. The answer supplies the unique-isomorphism argument from the universal property, uniqueness/naturality of the Boolean character, the fully faithful comparison for common-scalar algebra maps, and the commuting coordinate-origin diagram. It retracts the bare-C test and repeated-adjunction replacement.

What remained uncalculated. Source correction is not the requested cohomological realization or purity estimate. U0022 correctly insists that bottom uniqueness and higher nullity coexist; both claims must be propagated into subsequent work rather than alternately substituted.

Exact obstruction scope. Uniqueness over a fixed universal input is proved. Equality of dimensions, empty fibres, or Boolean observations does not identify arbitrary higher objects; conversely their distinction is no obstruction to a common base.

Concrete surviving derivation. The exact present continuation is the four-point P with all support fibres T_A over b_τ , the structural map, A_τ and res_σ comparison. No fresh bottom support should be invented for each mask or degree.

228.3.12 BF12 — A0862 §§1-2

User U0022 (b48b70f3-9b82-48fc-b7b9-d3e6fd428c42); assistant A0862 (b6c3dc97-18dd-487e-bb70-933fab060c64), chain 1745; passage line 3387. Priority 1.

There is a direct contradiction proving that the supported-zero ideal cannot receive a finite positive multiplicative norm

Status: completed original-object norm rigidity; scope exact.

Requested calculation. Keep bottom-support uniqueness while using the infinite quotient to calculate a real rigidity statement relevant to the whole arithmetic system.

Original objects and maps. $S=G(O_K)$, e-ideal $\mathfrak{e}=\{\tau, e\}$, supported ideal monoid $\{I_J\}$, $\mathfrak{e} I_J = \mathfrak{e}$; norm map to $[1, \infty]$.

What was actually proved. The absorption argument proves uniqueness in that specified ideal monoid. Since $N(2R) = 2^{[K:Q]} > 1$, a positive finite extension q would obey $q = 2^{[K:Q]} q$; hence the multiplicative extension has $N(\mathfrak{e}) = \infty$. The converse assignment and multiplication are checked.

What remained uncalculated. This exact result does not compute the sign or growth of arithmetic zero cohomology. The infinite norm alone does not define a geometric proper direct image or identify every possible F1 object.

Exact obstruction scope. The contradiction excludes finite positive norms with those operations and retained ordinary norms. It neither disproves nor proves the original purity program.

Concrete surviving derivation. Use the preserved arithmetic square as structural input to b_τ . Retain the source infinity value and prove how arithmetic operators act on $A_\tau(T)$; do not replace the norm by a finite mass or derive weights from its cardinality.

228.3.13 BF13 — A0862 §3

User U0022 (b48b70f3-9b82-48fc-b7b9-d3e6fd428c42); assistant A0862 (b6c3dc97-18dd-487e-bb70-933fab060c64), chain 1745; passage line 3682. Priority 0.

The contradiction concerns finiteness while preserving the specified arithmetic kernel

Status: completed quotient classification at exact zero fibre.

Requested calculation. Compute what a finite quotient at the distinguished support would do while preserving the original arithmetic.

Original objects and maps. $q:G(O_K)\rightarrow T$ unital, zero fibre exactly $\epsilon=\{\tau,e\}$; $p:G(O_K)\rightarrow O_K$; $\chi:G(O_K)\rightarrow B$ with zero fibre $\{\tau\}$.

What was actually proved. The restriction of q to O_K is a ring map, is injective by the exact zero fibre, and is surjective; therefore $T\cong O_K$ and is infinite. Finite arithmetic quotients instead have enlarged zero fibre I_J ; the finite Boolean observation has a different zero fibre and collapses all supported amplitudes.

What remained uncalculated. No uniqueness theorem for all F1 candidates or all infinite quotient cardinalities follows. No spectrum/weight transfer is calculated.

Exact obstruction scope. This excludes a finite quotient with precisely that kernel. It does not identify the structural base map with the Boolean generic-stalk restriction.

Concrete surviving derivation. Keep the later source's opposite-direction maps $j_{\text{math}_R}:F_{\{1,\tau\}}\rightarrow B_R$ and $\chi_R:G(R)\rightarrow B$. The first defines the absolute base; the second defines res_σ . Calculate their actual derived comparison, not an identity between them.

228.3.14 BF14 — A0862 §§4–5

User U0022 (b48b70f3-9b82-48fc-b7b9-d3e6fd428c42); assistant A0862 (b6c3dc97-18dd-487e-bb70-933fab060c64), chain 1745; passage line 3835. Priority 0.

It does not yet determine the sign of that full trace pairing.

Status: all-character support calculation advanced; analytic task interrupted.

Requested calculation. Propagate norm rigidity through every character and use it to study the full arithmetic rigidity mechanism.

Original objects and maps. $w_{\{\chi,s\}}(I_J)=\chi(J)N(J)^{-s}$; $\epsilon I_J=\epsilon$; $C[I_m\cup\{\epsilon\}]\cong C\times C[I_m]$; the retained arithmetic trace representation W .

What was actually proved. For $\text{Re } s>0$, a weight with $|\chi(J)N(J)^{-s}|<1$ forces $w(\epsilon)=0$. The direct-product algebra preserves the support idempotent and entire ordinary ideal algebra. This proves the exact zero contribution of that idempotent to those particular weights.

What remained uncalculated. The response then quotes the GRH-equivalent trace-positivity criterion and stops. It has not derived the full trace from the theta source, analyzed its sign, or shown that the kernel carrying actual spectral classes vanishes.

Exact obstruction scope. Zero weight on the absorbing ideal is not zero cohomology or zero spectral trace on the original quotient Q . The later source explicitly retains $H_1(T_A)=Q$ for every nonempty mask.

Concrete surviving derivation. Compute the full Mellin-jet trace contraction $R_Z(f,j_g h)=\sum m_\rho \text{conjugate}(f(1-\bar{\rho}))h(\rho)$ within $K_\tau(L_1)$, with the full g -unit and supported zero functionals. Any vanishing of a larger kernel must be proved by its actual test traces.

228.3.15 BF15 — A0952 opening; corrected reading route A0961

User U0027 (b48fac36-14fb-4a9b-a6fe-7d6fe8b94886); assistant A0952 (50a6a43b-ec70-40dc-b17f-864477ddcff4), chain 1985; passage line 3897. Priority 1.

I checked eight of those pages against the original French scan.

Status: source provenance repaired in stages; requested TeX-only route not followed by this account.

Requested calculation. U0025 challenged the claimed reading; U0026 required restart; U0027 explicitly required unpacking and reading LaTeX, with no PDF/OCR.

Original objects and maps. The nested six-part S20 archive, English/French historical TeX witnesses, their $j_!/j_*$ and dual-weight sign discrepancies; original scan checks are reported by the assistant.

What was actually proved. A0877 and A0952 retract the unestablished reading claim. A0952 reports a bounded 32-page text reading and eight scan checks rather than a full-paper audit. A0961 then explicitly uses the retained TeX and documents witness disagreements.

What remained uncalculated. This segment itself cannot verify every historical source-access claim or every attached package. A0952's reported scan checks do not comply with the immediately preceding TeX-only instruction. A0961 improves the source route but its reading remains section-bounded.

Exact obstruction scope. A source-reading defect is not a mathematical counterexample. It limits what the reported comparison establishes and requires exact witness pins; it does not license stopping the original program.

Concrete surviving derivation. Cite the actual retained French theorem text and exact ranges for the signs/maps used, keep historical English discrepancies visible, and calculate the comparison on the original tau objects. Do not repeat the source-reading cycle after sufficient source evidence is acquired.

Later repair or steering: A0961 opening and §§5.2–5.4.

228.3.16 BF16 — A0952 §§1–2

User U0023 (c1f5c457-5da2-439d-b133-0a4b032008ed); assistant A0952 (50a6a43b-e70-40dc-b17f-864477ddcfff4), chain 1985; passage line 4140. Priority 0.

a functor identifying your full mixed-double multiplication with Deligne's sheaf operations has not been constructed

Status: relevant source correspondence advanced; actual functor unfinished.

Requested calculation. Map the complete mixed-support structure into the analogous Deligne argument over one privileged base while retaining all directions.

Original objects and maps. Deligne common intersection E , Kummer cover X_m , $F[E]$, commuting N_i , successive specialization isomorphism; split mixed double D_A with X_a, Y_b, Z_z and four masks.

What was actually proved. The answer identifies the actual multi-direction specialization and coherence theorem. It gives mixed-double multiplication, amplitude r_D , Boolean group-semiring support map, and subset-to-bitvector bijection. This is more informative than treating all directions as fresh scalar zeros.

What remained uncalculated. The only explicit cross-comparison here is the incidence-label bijection. It is not a functor carrying sheaves, mixed-double multiplication, monodromy, derived global sections, or the arithmetic action.

Exact obstruction scope. No obstruction to a full functor is established. A failure to have constructed it cannot be promoted to nonexistence or to failure of the tau-base program.

Concrete surviving derivation. The later actual realization supplies T_A on P , reconstructed SplitZero sheaf, global functor A_τ and K_τ . Use those concrete objects as the domain of the comparison, preserving each mask and precomposition arrow, then calculate monodromy/scaling compatibility rather than identifying labels with weights.

228.3.17 BF17 — A0952 §§3,5

User U0023 (c1f5c457-5da2-439d-b133-0a4b032008ed); assistant A0952 (50a6a43b-e70-40dc-b17f-864477ddc ff4), chain 1985; passage line 4352. Priority 0.

I have not established that your split-zero construction realizes these sheaf categories

Status: Deligne mechanism identified; original-object calculation deferred.

Requested calculation. Develop the analogous cohomological proof over τ , including duality, mixed support, specialization and weight transfer.

Original objects and maps. $c_i : H_c^i \rightarrow H^i$, image I^i ; upper bound $n+i$, lower bound from $F^\vee$ and twist (d); $K_X = \text{Ra}^! Q_L$; proper potentially-pure specialization in §6.2.9.

What was actually proved. The answer preserves the two bounds on one image, the $2d-i$ index, both dual signs and twists, and the invariant-cycle target $H^*(X_{\text{bar}\eta}, K)^{\text{Gal}}$. It recognizes that singularity need not destroy duality in the stated rational-homology-manifold setting.

What remained uncalculated. No c_i for the actual theta sheaf, no extraordinary pullback or involutive duality on the original arithmetic category, and no two-sided arithmetic weight bounds are constructed in this response. The potentially-pure hypothesis of the quoted specialization theorem is not proved for the proposed system.

Exact obstruction scope. The quoted theorem proves results for its declared proper arithmetic setting. A common base point or infinite quotient does not itself satisfy those hypotheses. Conversely, the lack of that literal category identification does not disprove an analogous construction.

Concrete surviving derivation. Compute the actual A_τ right adjoint K_τ , its unit/counit and comparison with restriction; use the established finite-jet injection into its derived Hom. Distinguish this proved adjunction from unproved involutive local duality and calculate the surviving analytic bound directly.

228.3.18 BF18 — A0952 §4

User U0023 (c1f5c457-5da2-439d-b133-0a4b032008ed); assistant A0952 (50a6a43b-e70-40dc-b17f-864477ddc ff4), chain 1985; passage line 4295. Priority 0.

tensor amplification, geometric control, and an error bound that decreases under iteration

Status: actual Deligne amplification identified; arithmetic bound not calculated.

Requested calculation. Reproduce the proof mechanism on the original split cohomology at the privileged τ base, rather than only describe purity.

Original objects and maps. Deligne bound $w_q(\alpha) \leq 1 + 2^k(-k)$, the tensor-square inclusion and Lefschetz-pencil estimate. The successor Tau_Base uses P^r , signed tensor differential, $Q^\vee \otimes r$ and $a^r(r\rho)$.

What was actually proved. The answer correctly identifies how a fixed positive excess contradicts a bound with shrinking error. A0961 further retains the even tensor powers, nonnegative traces, determinant pole argument and $r+1/k$ estimate.

What remained uncalculated. The geometric upper estimate has not been derived for the original characteristic-zero theta source. In the successor source the amplification itself is completed but equation (50) explicitly leaves its bound unproved.

Exact obstruction scope. Failure to have that estimate is an unfinished calculation, not evidence that every possible τ -base argument fails. A bound tested on a later auxiliary polynomial family has its own scope.

Concrete surviving derivation. Use the already proved top tensor $Q^\wedge \otimes r$ and $K_{\{\tau, r\}} = S_{(\eta, \dots, \eta)} W[r]$, retaining the original Koszul signs. Derive an actual bound on $r(2\text{Re}\rho - 1)\log a$ from the original theta relations and analytic boundary terms; do not assume sublinear growth.

Later repair or steering: $\text{Tau_Base } \S 7$ completes amplification, not its bound.

228.3.19 BF19 — A0961 §§1–3

User U0023 (c1f5c457-5da2-439d-b133-0a4b032008ed); assistant A0961 (a7bbd422-311c-4380-ba6c-a4bdd61fce2f), chain 2032; passage line 4500. Priority 1.

the idempotent synchronizes support and preserves amplitudes.

Status: completed mixed-object localization; discarded support observation must remain explicit.

Requested calculation. Perform an actual operation on the original mixed support and compare what it preserves with the proposed purity mechanism.

Original objects and maps. $D_A = G(A)^\wedge 2$, $E = (1, e)$, $D_A[E^\wedge(-1)] \cong G(A[t]/(t^2+1))$; (Chi, π) injective; higher $D_{\{A, n\}}$, $E_n = (1, e, \dots, e)$.

What was actually proved. The answer proves the multiplication formulas, the synchronization localization universal property, and injectivity of the joint support/amplitude observation. E sends every nonempty mask to the synchronized face while preserving the amplitude. The full n -formulas retain $u = -1$ and all wrap exponents.

What remained uncalculated. Localization forgets which nonempty face the input occupied. Its coefficient-amplitude identity does not calculate a cohomological image, trace sign or weight inequality. No kernel/cone of this observation on the original theta complex is computed here.

Exact obstruction scope. This is a real morphism with a calculable information loss. It neither deletes arbitrary spectral packets nor forces their vanishing. It is not the same as the structural pushforward A_τ .

Concrete surviving derivation. Carry the maps on the complete mask diagram T_A , record the nonempty-mask saturation separately from coefficient maps, and compute induced kernel/cokernel or cone. Keep A_τ and res_σ distinct as in the successor (19)–(25).

228.3.20 BF20 — A0961 §4, completed purity calculation

User U0023 (c1f5c457-5da2-439d-b133-0a4b032008ed); assistant A0961 (a7bbd422-311c-4380-ba6c-a4bdd61fce2f), chain 2032; passage line 4690. Priority 0.

This gives **weight-zero purity of this coefficient object**.

Status: valid coefficient calculation; no arithmetic spectral transfer.

Requested calculation. Obtain a Frobenius-like arithmetic spectrum and prove the requested purity for the original zeta cohomology.

Original objects and maps. $B_{\{A, n\}} = A[t]/(t^{n+1})$; reductions $O_K \rightarrow k_p$; Φ_q with the exact coefficient sign $u^{\lfloor q_i/n \rfloor}$; $Y_n = \text{Spec}(F_q[t]/(t^{n+1}))$, $\gcd(q, 2n) = 1$.

What was actually proved. The response computes the affine permutation $j \mapsto qj + (q-1)/2 \pmod n$, geometric Frobenius as its inverse, and $\det(1 - \text{TF}|H_0) = \prod (1 - T^{d_j})$; thus this finite reduced coefficient spectrum has roots of unity. It explicitly retains primes dividing $2n$ outside the calculation and supported residue zeros under reduction.

What remained uncalculated. There is no map from $Q=B/\Theta V$, its H1 scaling representation or full Mellin jets to this finite H0 permutation representation which identifies the desired weight. The degree change $1 \rightarrow 0$ and coefficient change $C \rightarrow F_q$ are not bridged.

Exact obstruction scope. The stated weight-zero result is correctly scoped to Y_n . It cannot prove purity of the original theta spectrum, and a failure of a later t^{n+1} variant cannot disprove it. This family must not replace $g=2\xi$.

Concrete surviving derivation. Return to the original $T, A_{\tau}(T)$ and full actual zero packets. If using a finite-prime model, construct its integral lattice and actual specialization/trace map; otherwise calculate the characteristic-zero scaling bound directly. No unital map $C \rightarrow F_q$ can supply coefficient reduction, since $p \cdot 1$ is invertible in C and zero in F_q .

228.3.21 BF21 — A0961 §6

User U0024 (65b8bdef - be04 - 4ac6 - a7f1 - 9bb25a8f74f4); assistant A0961 (a7bbd422 - 311c - 4380 - ba6c - a4bdd61fce2f), chain 2032; passage line 4906. Priority 1.

The force is translated too; this does not claim different locations with an unchanged prescribed force.

Status: legitimate exact NS symmetry obstruction.

Requested calculation. Test the claim that the original cancellation can occur only at the origin and hence forces a unique arithmetic support.

Original objects and maps. $R_{\nu}(u,p) = \partial_{\tau}u + (u \cdot \nabla)u - \nu \Delta u + \nabla p$; T_b on the full (u,p,f) ; disjoint translates with all supports retained.

What was actually proved. The exact translation commutes with the full residual, divergence and spatial norms. Under the stated compact/disjoint supports the nonlinear cross terms vanish and squared energies add. It transports the marked center while translating the force.

What remained uncalculated. The answer does not determine all possible blow-up locations for a fixed original force. It also supplies no map from the NS triple to the unique arithmetic support or the theta cohomology.

Exact obstruction scope. It refutes universal coordinate-origin uniqueness for the translation-stable class of full triples, not a fixed-force uniqueness claim or the existence of an intrinsically marked support in another model.

Concrete surviving derivation. Retain the proved symmetry and specify whether the proposed arithmetic marking is invariant, equivariant, or tied to a fixed force. Any renewed NS transfer must carry the full force and residual; translating only the velocity cannot serve as that map.

228.3.22 BF22 — A0961 §7

User U0024 (65b8bdef - be04 - 4ac6 - a7f1 - 9bb25a8f74f4); assistant A0961 (a7bbd422 - 311c - 4380 - ba6c - a4bdd61fce2f), chain 2032; passage line 5010. Priority 0.

Unipotent behavior organizes the boundary grades; it does not erase them or fix their center by itself.

Status: completed arbitrary-length block calculation; literal action comparison missing.

Requested calculation. Relate unipotent support and the complete higher-direction ladder to the arithmetic weight needed in the proposed proof.

Original objects and maps. $Nv_0=0, Nv_j=v_{\{j-1\}}, Fv_j=cq^jv_j$; $FN F^{(-1)} = q^{(-1)}N$; grade $2j-d$, center $\gamma+d$. Original $\text{Tau_Base}(40)$ instead has $Nz^j = z^{j+1}, U_a = a^{\rho} \exp(\log(a)N)$.

What was actually proved. The answer retains all block lengths $d+1$, the actual monodromy twist and the free center scalar c . Multiplication of F by q leaves monodromy and relative filtration unchanged while shifting absolute weights; hence this monodromy data alone does not fix the center.

What remained uncalculated. No map from the original theta action or NS correction operator to this F, N pair is calculated. In particular the original scaling commutes with its jet N , whereas this F scales N by $q^{(-1)}$.

Exact obstruction scope. The result obstructs an inference of absolute weight from unipotence alone. It is not a broad obstruction to adding the missing arithmetic dynamics or to the original tau cohomology.

Concrete surviving derivation. Calculate the exact full-jet comparison: $U_a N U_a^{(-1)} = N$. A simultaneous intertwiner with the displayed Deligne pair kills N . On the original germ $g = u(z)z^m$, the separately defined $C_q f(z) = f(z/q)$ retains the unit ratio $q^{(-m)}u(z/q)/u(z)$, gives $C_q N C_q^{(-1)} = q^{(-1)}N$ and $C_q U_a C_q^{(-1)} = a^{\rho(1-1/q)} U_{a^{1/q}}$. This is a surviving semidirect comparison, not an arithmetic weight theorem.

228.3.23 BF23 — A0963 closing progress node

User U0028 (9d5e82ea - d670 - 4145 - b5d3 - c22d8948133e); assistant A0963 (6c82ae69 - e025 - 419b - ac36 - a20d2cf62f4c), chain 2036; passage line 5036. Priority 0.

I'm continuing the global construction

Status: open segment boundary; continuation owned by later transcript.

Requested calculation. Continue mapping all original split-zero and Spec Z objects into the analogous Weil II proof; do the work before judging the program.

Original objects and maps. The user explicitly selects the privileged absolute base, the whole supported spectrum above it, original arithmetic preservation, and the analogue of the proof rather than the literal finite-field theorem.

What was actually proved. This node states the intended next work on sheaves, duality and arithmetic trace. It contains no completed calculation.

What remained uncalculated. The substantive answer to U0028 lies beyond this assigned segment. It is not legitimate to call the absence of that answer inside the segment an abandonment of the full session.

Exact obstruction scope. No obstruction or program verdict occurs in this closing node.

Concrete surviving derivation. Carry U0028 as an active request into the following segment. The current continuation must start from the later Tau_Base construction rather than restart the source-discovery and finite-coefficient detour.

228.4 Exact continuation route already supplied by the later source

The absolute base is the pointed blueprint $F_{\{1, \tau\}} = \{\tau, 1\}$, with structural map induced by j_{math_R} , not the Boolean localization at the generic stalk. The original four-point upper-set space has $+\langle \eta \rangle \sigma$ and $-\langle \eta \rangle \sigma$. Its fibre category computes $A_{\tau}(F) = [F_+ \oplus F_- \rightarrow F_{\eta}]$ with differential $r_+ - r_-$. The separate $\text{res}_{\sigma}: A_{\tau}(F) \rightarrow F_{\sigma}$ has two degree-zero representatives whose difference is $r_{\{\eta \sigma\}}(r_+ - r_-)$, retaining the chain homotopy.

For the original theta sheaf T , the complex is $[V \oplus V \rightarrow B]$, $d(\varphi, \psi) = \Theta(\varphi - \hat{\psi})$. Its H_0 is V by $\psi \mapsto (\hat{\psi}, \psi)$; $H_1 = Q = B/\Theta V$. Every nonempty mask has the same H_1 coefficient Q ; single-leg H_0 is zero while joint-mask H_0 is V . The split lift retains tau separately from each labelled supported zero. The derived comparison with σ does not delete these classes.

$K_{\tau}(W)=[I_{\eta}(W)\rightarrow I_{+}(W)\oplus I_{-}(W)]$ in degrees $-1,0$ has $(+res,-res)$, and is quasi-isomorphic to $S_{\eta}W[1]$. The original source action is $(\varphi,\psi)\mapsto(U_a\varphi,aU_{\{1/a\}}\psi)$, with $U_aF(x)=F(x/a)$; both legs and the factor a are required. The L1 moment representation supplies the twist in the dual action.

The actual finite quotient $Q\rightarrow A_Z$ retains $g=2\xi$ and all local multiplicities. The residue form with reflected-germ signs $(-1)^j$ gives the injective map of the conjugate full packet into $\text{Hom}(Q,L1)=H^*(-1)\text{RHom}(T,K_{\tau}(L1))$. The trace contraction uses multiplication by the actual g' and is not the perfect residue form. Product charts retain every Koszul sign and yield $Q^{\wedge}\otimes r$ and $S_{(\eta,\dots,\eta)}W[r]$. These constructions are completed mathematics; the arithmetic growth estimate is the remaining calculation, not an assumed theorem.

228.5 Prioritized redo instructions for integration

1. Resume those actual A_{τ} and K_{τ} objects. Carry all masks and maps; do not replace the pushforward by σ restriction, the origin ladder by repeated adjunction, or the arithmetic quotient by the finite t^{n+1} coefficient example.
2. Complete the derived restriction fibre/adjoint comparison and its induced supported cohomology maps. Every supported class that maps to a labelled zero must retain its exact source fibre and kernel contribution.
3. Put the full original Mellin-jet injection, raw residue orientation, trace contraction and actual two-leg scaling into that comparison. Do the analytic theta calculation, including endpoint terms and gamma arithmetic, that a tensor estimate would require.
4. Preserve every legitimate obstruction above at its proved scope. In particular the non-arithmetic quartet test, smooth curved filling and finite H_0 purity result cannot determine the fate of the original theta H_1 program.
5. If comparing full jets to Deligne monodromy, calculate the exact action relation recorded in BF22. A literal identification silently kills nilpotents; the semidirect coordinate-dilation comparison survives with its stated extra action and original unit.
6. Carry U0028 into the following transcript segment. Do not count this segment boundary as an abandoned answer, and do not repeat source-reading apologies after the relevant source route has been acquired.

228.6 Completed tractable calculation delivered to root

BF22 isolates an algebraic calculation on the original finite jet packet, rather than a new polynomial family. The original U_a commutes with multiplication by z . The separately constructed $C_q:f(z)\mapsto f(z/q)$ respects the exact ideal (g) because $g(z/q)/g(z)=q^{(-m)}u(z/q)/u(z)$ is a unit. It is invertible, with $C_q^{(-1)}f(z)=f(qz)$. Thus $C_qNC_q^{(-1)}=q^{(-1)}N$ and $C_qU_aC_q^{(-1)}=a^{\rho(1-1/q)}U_{a^{1/q}}$. The comparison retains the same ρ , z , m and unit u . It does not identify C_q with the original arithmetic action.

The complete new proof is GERM_GRADING_AND_THETA_LIFT.md, with standalone TeX and an inclusion fragment alongside it. It also computes the full reflected residue Jacobian and adjoint, preserves the exact g -prime contraction, constructs an explicit compact-support Mellin right inverse by an invertible Gram matrix, and lifts C_q to a continuous automorphism $L_q=I+S(C_q-I)_Z$ of the ORIGINAL two-leg theta sheaf, with uniform forward seminorm bounds for $q\geq 1$. The lift fixes Theta V and all masks and has a proved comparison into the existing K_{τ} dual. Its noncanonical section-dependence and inverse growth are recorded. GERM_PAIRING_CHECK.md is an independent full algebra review; its eight exact fixtures and mutation controls are auxiliary verification.

No shared master, remote service or Lean process was changed by this lane.

229 Typed route: U0029–U0040

230 Passage-by-passage typed-route audit: U0029–U0040

This is a mathematical continuation audit of the full assigned transcript segment. It makes no inference about the model’s motives. Exact short passages and UUIDs below are checked against the final source extraction. Later corrections are part of each finding.

230.1 Coverage and source provenance

The assigned segment contains 12 user turns and 22 assistant turns, including progress replies, in exact retained order. All were read. Final extraction: 159,410 bytes, SHA-256 `a6574b90b21cd3e46533cc9aee7dc3ef8874dfa7a0860df93cc458c1bf1500e9`. The first full reading used the pre-newline-repair hash recorded in the JSON; root subsequently removed doubled CR/LF translation without changing message text. Quotes were revalidated after that repair.

The complete primary Tau Base NOTE.md (SHA-256 `d03e71ad18f187bd89880cb8ca6fc9c5d6f260b3de8e8e5702c27db97e7b63c3`) and complete canonical source route (SHA-256 `a8cdd18817a2c3596778c60a04ef9d76125a03ae5404759835a2bc2b18fa4c74`) were read. Dependencies named in those sources are not thereby claimed as freshly read in full. The companion source-map verifier separately read `support_diagrams.tex` in full and supplied its proofs and source pins.

The ledger’s ‘actual result’ states the scope of the displayed argument, independently checking its elementary typed algebra. This audit does not claim a fresh independent verification of all cited external books, every historical package, or historical test counts. Root owns the separate analytic and replay lanes.

230.2 Controlling continuation

The current primary construction is the structural blueprint map $F1, \tau \rightarrow B_R$ and its spectrum map to $b\tau$; the four-point upper-set chart; $A\tau = R\Gamma(P, -)$; the distinct derived restriction res_σ ; the complete supported H^1 fibres carrying Q ; $K\tau \simeq S_\eta W[1]$; the full-jet map $Q \rightarrow A_Z$; the residue injection into $R\text{Hom}(T, K\tau(L1))$; and actual tensor powers $Q \otimes r$. They are equations (1)–(50) of the primary source, not missing hypotheticalal objects.

The earlier transcript predates that completed primary note. Its missing-arrow statements must be updated using the later exact constructions rather than repeated as the present state. In particular Boolean generic-stalk restriction is a proved comparison with $A\tau$, not its definition or replacement.

An additional typed comparison is now completed: the finite-quotient argument alone places the socle eigenline in $A\rho$, but original `arithmetic_input.tex` (A10)–(A11) already supplies $\text{sigma} = qR_ref: E_h \rightarrow Q[h(D)]$, with $Jbar_Z$ $\text{sigma} = \text{id}$ and the complete unit $\text{epsilon} = j_h(h/g)$. The proved finite cocycle $U_aR_ref - R_ref$ $a^A = \text{Theta } c_a$ establishes equivariance for every positive a . The full source lift is therefore $L\rho = \text{sigma } \text{iota } \rho$ $t\rho: C \rightarrow Q$, and its tensor is a nonzero equivariant injection into $Q \otimes r$. Section 8 of the companion source-map proof gives the complete original construction, source estimates, retained boundary, full jet insertion, explicit left inverse, and tensor homotopy signs. The earlier quotient argument’s limited scope is retained; the source eigenline lift is no longer described as missing. The upper weight estimate remains a different calculation.

230.3 Every user-response episode

230.3.1 U0029 — 53352f69-6c38-4cab-a6aa-c225647ebe9a

A1007 announces the concrete sheaf lift; A1021 performs multiplication, gluing, support-prime restriction, nonsplitting, and the supported-null-cycle construction. T01 records its exact scope.

230.3.2 U0030 — 2e3cac15-6cbf-4fbd-b826-ceed04867399

A1022/A1032 announce the adelic reduction and retention of global norm errors; A1070 constructs HN/spectral filtration lifts, Rees defects, and slope diagnostics. The arithmetic theta specialization remains missing (T02–T04).

230.3.3 U0031 — fd1d4ef4-537b-4bca-8d5b-0cb82a441737

A1071/A1098/A1106 announce the Rees amplification and trace work; A1140 supplies the uniform-family formulas and explicitly admits the absent global cohomological identification. T05–T06 preserve this limit.

230.3.4 U0032 — f4609209-f2cd-4dbc-8ec2-a8995aedc998

A1142/A1155 explicitly turn to the actual theta source; A1167 supplies the real extension-by-zero, raw analytic realization, smooth full-jet right inverse, and quotient Gram metric (T07–T09). This partly repairs U0031.

230.3.5 U0033 — 622780af-97a6-4c56-987c-135df8409461

A1169 promises original-congruence propagation; A1206 supplies the internal coequalizer, relation-labelled quotients, transition kernels, actual differentiated theta endpoint families, and support-preserving operators (T10–T11).

230.3.6 U0034 — b5ee7e11-a089-4433-af7a-ed73bbc5bcf

A1210 announces reconciliation with the spectral paper; A1235 changes the primary target to unshifted Weil positivity, computes its exact shift correction, quotient correspondence, and residual/gap comparison, then leaves the central analytic term unestimated (T12–T15).

230.3.7 U0035 — 7b9f7612-3a57-4687-9bfb-39d1d933baf8

This action-continuity correction has no separate substantive assistant reply before U0036. It jointly controls A1280, which acknowledges and repairs the program displacement (T16).

230.3.8 U0036 — d6542f7d-b917-4de5-b35d-07062f16e9c1

A1280 restores cohomology/action/Lefschetz order, constructs correspondence saturation and full-jet traces, and retains moment endpoints and the explicit-formula terms. It explicitly leaves infinite cohomological trace and geometric endpoint-degree identifications unproved (T17–T18).

230.3.9 U0037 — 8b2110e7-195b-42d0-8c86-7277004e35fd

This demand to apply the program is followed by U0038 before a substantive reply. A1304 responds to both with actual mixed-source endpoint-image and residue calculations; T19 records the result and overstatement.

230.3.10 U0038 — 4ab2ff8f-915a-417d-876f-7294ed662b24

A1304 computes all masks, source-induced c_m , endpoint duality, and the J_g trace contraction. Its statement that Deligne had been applied is narrower in its own caveat and later corrected in A1361/A1427 (T20–T21).

230.3.11 U0039 — 71c1d5ee-668e-4eea-ac21-d844702248ea

A1306 announces the requested audit; A1361 supplies concrete raw-realization, Frobenius, cohomological-degree, residue-orientation and checker corrections, and preserves their limited scope (T22–T26).

230.3.12 U0040 — a10456e9-7f72-4c81-bc00-118fcd575269

A1362 announces source/F1/Deligne checking; A1427 supplies actual blueprint/prime/completion maps, proves raw-kernel nonvanishing, constructs balanced realization and finite-jet isomorphisms, and accurately limits its Deligne application status (T27–T30).

230.4 Exact passage ledger**230.4.1 T01: completed exact replacement; no obstruction to original program**

User: U0029 (53352f69-6c38-4cab-a6aa-c225647ebe9a, chain 2057). **Reply:** A1021 (cf9ad54a-2906-4d48-9cbd-b9e9677bb362, chain 2138).

Its failure to admit that natural section is information about the extension itself. It is not a reason to discard the extension.

Requested calculation. When a map fails, construct the typed relation and strongest surviving replacement.

Original objects and maps. $H_G(Q) \rightarrow H_Q$, archimedean ℓ_1 -bounded Γ -objects, split sheaf pull-back, added support prime σ .

Actual result and proof scope. The fold on $(1/2, -1/2)$ obstructs a pointed natural section. The pullback sheaf itself exists, glues, retains τ/e , and maps to the original arithmetic sheaf.

Left uncalculated. This episode defines a supported-null cycle object but computes neither its higher derived cohomology nor a weight bound.

Exact obstruction scope. Only a section of this particular pointed natural projection is excluded. The sheaf extension survives.

Later completion or correction. A1206 computes the internal coequalizer; A1280 installs correspondence action; the later primary τ -base note computes $A\tau$ and $K\tau$.

Concrete surviving derivation. Use the existing support-reconstructed theta sheaf (primary (14)–(25)) and its actual derived pushforward, retaining the pullback rather than trying to split it.

230.4.2 T02: correct general construction; arithmetic specialization left uncalculated

User: U0030 (2e3cac15-6cbf-4fbd-b826-ceed04867399, chain 2139). **Reply:** A1070 (86b375dc-bd7b-494b-b050-0d8680eadae0, chain 2308).

For a compatible supported graded algebra

Requested calculation. Push the richer supported adelic construction toward Weil II/RH.

Original objects and maps. Adelic bundle E with actual place norms, HN filtration, spectral norm, supported graded algebra $M_\bullet \rightarrow E_\bullet$, Rees modules.

Actual result and proof scope. Pullback filtrations retain the full amplitude-zero fibre; the two norm assignments are connected by the displayed error bound; multiplicativity is proved for the stated graded input.

Left uncalculated. No actual adelic norm family or graded comparison is supplied for the original theta complex Q . The phrase introduces an input instead of deriving that input from the source.

Exact obstruction scope. HN and spectral norms may be different; the recorded inequalities do not authorize replacing the original metric or transferring their bounds to Q .

Later completion or correction. A1167 supplies a genuine finite theta-quotient Gram metric but explicitly leaves its adelic realization unbuilt; A1361 audits the missing HN/spectral intertwiner.

Concrete surviving derivation. Attach each chosen norm to a concrete finite quotient of $A_T(T)$, retain its exact comparison with the original theta measure, and calculate the corresponding map height before using Chen–Moriwaki.

230.4.3 T03: legitimate measured obstruction; vanishing unproved for arithmetic map

User: U0030 (2e3cac15-6cbf-4fbd-b826-ceed04867399, chain 2139). **Reply:** A1070 (86b375dc-bd7b-494b-b050-0d8680eadae0, chain 2308).

It replaces the unproved assertion that every such comparison is automatically strict.

Requested calculation. Construct the supported comparison relevant to purity.

Original objects and maps. $c: (V, F) \rightarrow (W, G)$, $I = \text{im } c$, quotient/subspace filtrations $F_q \subset F_s$, $D_c = \text{Rees}_{F_s}(I) / \text{Rees}_{F_q}(I)$.

Actual result and proof scope. For integer jumps D_c is finite T -power torsion and $\text{length}(D_c) = \sum \mu - \sum \lambda$; the special-fibre Tor sequence retains its kernel and cokernel. For the actual spectral-weight filtration, an equivariant map is strict by generalized eigenspaces.

Left uncalculated. The transcript has not identified this c and filtration with the arithmetic theta comparison or proved their strictness.

Exact obstruction scope. The rank-one source-weight 0/target-weight 2 example disproves automatic strictness of arbitrary filtered maps only.

Later completion or correction. A1140 amplifies this exact defect; A1361 explicitly retains separate HN and spectral filtrations.

Concrete surviving derivation. Compute the induced map on the finite Mellin-jet quotients of the original cohomology together with its actual source/target filtration. If the filtration comes from scaling, prove equivariance using the full nilpotent operator before computing D_c .

230.4.4 T04: complete diagnostic; different example family is not arithmetic proof

User: U0030 (2e3cac15-6cbf-4fbd-b826-ceed04867399, chain 2139). **Reply:** A1070 (86b375dc-bd7b-494b-b050-0d8680eadae0, chain 2308).

The appropriate replacement for a mean-only invariant is now explicit

Requested calculation. Obtain the purity information of the arithmetic construction.

Original objects and maps. $C_V(c) = \sum \max(\lambda_j - c, 0)$, endomorphism norm, weighted Gauss metric on $H^0(P^1, \mathcal{O}(n))$.

Actual result and proof scope. Distributional second derivative recovers all slopes; $\deg + \text{End}(E_n) = |\alpha - \beta|n(n+1)(n+2)/6$ while the Hilbert–Samuel leading coefficient is $\alpha + \beta$.

Left uncalculated. No map identifies this chosen P^1 metric family with the original theta cohomology or gives its arithmetic weight distribution.

Exact obstruction scope. The example shows only that a mean invariant does not determine all weights. It is not a counterexample to τ -base purity.

Later completion or correction. A1361 preserves these calculations but removes any unsupported transfer to the arithmetic comparison.

Concrete surviving derivation. Retain the diagnostic formulas, apply them only after the concrete arithmetic filtration and operator have been constructed, and do not substitute the P^1 family for T .

230.4.5 T05: amplification completed; requested estimate transfer still missing

User: U0031 (fd1d4ef4-537b-4bca-8d5b-0cb82a441737, chain 2309). **Reply:** A1140 (4096bcde-e267-4ebe-8148-43bb2424da1a, chain 2445).

Their casting construction supplies the relevant kind of quantitative estimate

Requested calculation. Continue the calculation through tensor powers, duality, and the arithmetic trace.

Original objects and maps. $LQ \subset LP$, D_c , $\text{Sym}^m(I)$, actual Smith exponents.

Actual result and proof scope. $\text{length}(D_{\text{Sym}^m}) = \text{binom}(m+r-1, r) \text{length}(D_c)$; any bound on this very family sublinear per tensor degree would force $D_c = 0$.

Left uncalculated. No bound for this very comparison family is calculated. A sufficient inequality remains an unproved input.

Exact obstruction scope. The exact amplification law is valid. The law alone gives no vanishing and no weight estimate on $A_\tau(T)$.

Later completion or correction. The primary note (46)–(50) later computes actual Q tensor powers and their growth defect; that is the surviving original family.

Concrete surviving derivation. Apply tensor amplification to $Q \otimes r$ and $K_{\tau, r}$ from primary (47)–(48), and derive an analytic upper estimate from the original theta relations rather than import the casting bound by resemblance.

230.4.6 T06: explicit substitute family; gap acknowledged and later partly repaired

User: U0031 (fd1d4ef4-537b-4bca-8d5b-0cb82a441737, chain 2309). **Reply:** A1140 (4096bcde-e267-4ebe-8148-43bb2424da1a, chain 2445).

The uniform comparison family is constructed and its scalar trace identified.

Requested calculation. Connect the actual supported comparison to arithmetic cohomology and trace.

Original objects and maps. Uniform lattices $k[T] \otimes V \subset T^{\wedge}(-a)k[T] \otimes V$, shifted completed function $\Lambda(s - a\varepsilon)/\Lambda(s)$.

Actual result and proof scope. The grading derivative yields the defect trace; the chosen uniform family produces $-a\Lambda'/\Lambda$, with discriminant, primes, gamma factors and poles retained.

Left uncalculated. This construction chooses a uniform shift rather than deriving the global cohomological comparison; it does not compute the theta relation kernel or its weights.

Exact obstruction scope. It proves the scalar trace of that uniform family. Equality of scalar traces is not an isomorphism of the original comparison complexes.

Later completion or correction. U0032 explicitly says ‘So no map yet’; A1167 constructs the actual theta/extension-by-zero/Mellin map. Do not retain T06 as an entirely unremedied absence of any map.

Concrete surviving derivation. Use the actual source-induced arrows of A1167 and primary (19),(39),(43). Preserve any uniform-family calculation only with its typed comparison to those objects.

230.4.7 T07: actual extension-by-zero calculation completed

User: U0032 (f4609209 - f2cd - 4dbc - 8ec2 - a8995aedc998, chain 2446). **Reply:** A1167 (157eecd - 7f96 - 4ec5 - 96bd - 6dd376276ea6, chain 2520).

is the identity on

Requested calculation. Construct the missing actual map.

Original objects and maps. $C_+ = [V \rightarrow \Theta B]$, $C = [V \oplus V \rightarrow \Theta(\varphi - F\psi) B]$, $c_0(\varphi) = (\varphi, 0)$, $c_1 = \text{identity}$.

Actual result and proof scope. The chart extension-by-zero map induces identity on Q ; the source coordinate map $(\varphi, \psi) \mapsto (\varphi - F\psi, \psi)$ splits the joint complex as C_+ plus V in degree zero.

Left uncalculated. The displayed chart map is not identified with global arithmetic $f! \rightarrow f^*$. Its trivial H_1 comparison supplies no weight estimates.

Exact obstruction scope. An exact chart calculation, not the missing global geometric purity theorem. The nonzero H_0 joint summand must remain when passing back to $A_\tau(T)$.

Later completion or correction. Primary (18)–(22) incorporates this same joint theta complex in the four-point τ -base model.

Concrete surviving derivation. Carry the explicit joint complex through A_τ and K_τ ; retain $H_0 \cong V$ and the endpoint moment representations without renaming the latter as geometric H_0/H_2 .

230.4.8 T08: kernel formula correct; cohomological effect initially under-carried

User: U0032 (f4609209 - f2cd - 4dbc - 8ec2 - a8995aedc998, chain 2446). **Reply:** A1167 (157eecd - 7f96 - 4ec5 - 96bd - 6dd376276ea6, chain 2520).

Its kernel is calculated:

Requested calculation. Transport the actual theta quotient into the arithmetic divisor.

Original objects and maps. $\alpha: 0 \otimes V \rightarrow 0$, $\beta: 0 \otimes B \rightarrow 0$, $\delta = 1 \otimes \Theta$, $\beta\delta = g\alpha$, $g = 2\xi$.

Actual result and proof scope. The sheafified image ideal is (g) , α and β are sheaf-surjective, and raw realization $0 \otimes Q \rightarrow 0/(g)$ has kernel $\ker \beta / \delta \ker \alpha$.

Left uncalculated. The formula is not a proof that the kernel vanishes, and the raw tensor map is not shown to preserve full cohomology. ‘Image ideal’ concerns analytic O -linear sheaf generation, not equality of bare global Mellin images.

Exact obstruction scope. Only the quotient and its specified kernel are proved. Neither finite-jet surjectivity nor the generator φ^* erases that kernel.

Later completion or correction. A1361 gives the kernel complex and explicit raw syzygy; A1427 proves the raw kernel nonzero and supplies operator-balanced realization.

Concrete surviving derivation. Retain both raw and balanced realization maps and calculate their kernels as modules and complexes. The attached completed calculations give all-order syzygies and explicit free submodules of the raw kernel.

230.4.9 T09: finite quotient metric fully calculated; global metric bound not calculated

User: U0032 (f4609209-f2cd-4dbc-8ec2-a8995aedc998, chain 2446). **Reply:** A1167 (157eecd-f7f96-4ec5-96bd-6dd376276ea6, chain 2520).

The infimum over smooth compactly supported exact lifts is nevertheless the same

Requested calculation. Compute weight control on the actual source.

Original objects and maps. $H_R = L_2((e^{-R}, e^R), dx)$, finite Mellin-jet map, Gram matrix A, smooth bump right inverse.

Actual result and proof scope. All finite jets are surjective; A is positive definite; least-lift squared norm is $v^* A^{-1} v$; evaluation norm growth is $|\text{Re } \rho - 1/2|$. A correction by the smooth right inverse proves the same exact-lift infimum for C_c^∞ .

Left uncalculated. No global arithmetic comparison estimate bounds that growth or supplies an adelic metric inducing this exact norm.

Exact obstruction scope. A positive quotient metric always exists on finite observations; it is not the Weil trace form and does not establish spectral purity.

Later completion or correction. A1235 retains the unshifted form correction; A1361 warns against HN/spectral transfer.

Concrete surviving derivation. Keep dx , the $x^{1/2}$ map and all Gram coefficients. Estimate the actual theta relations in this norm, including boundary terms, rather than change measure or metric to force boundedness.

230.4.10 T10: requested internal quotient and transport kernels completed

User: U0033 (622780af-97a6-4c56-987c-135df8409461, chain 2521). **Reply:** A1206 (ea7fad65-aa59-4169-8bbd-5e73a631d3ae, chain 2613).

The quotient can now be taken in the original split-zero semimodule category

Requested calculation. Propagate the original split-zero quotient through every typed map.

Original objects and maps. $f=(\varphi, f_l): M \rightarrow N$, $B_k(f) = \sum_{\{\varphi(l) \leq k\}} \rho f_l(M_l)$, $\text{coeq}(f, \varepsilon f)$.

Actual result and proof scope. The original congruence yields coproduct $N_k/B_k(f)$, universal against arbitrary split-linear targets; finite relation labels give Q_W and transport kernel $\Theta W'/\Theta W \cong W'/W$.

Left uncalculated. Retaining these internal fibres does not itself calculate weight estimates, but that was not claimed as the new theorem.

Exact obstruction scope. This is substantive propagation rather than a label appended to an already collapsed ordinary quotient.

Later completion or correction. Canonical source E D6–D8 and primary (24)–(25) retain this result with categorical-kernel/all-support distinction.

Concrete surviving derivation. Use the same universal quotient for cohomology and every later realization, keeping bottom fibres and support maps explicit. Do not redo already proved quotient algebra as the purported missing purity calculation.

230.4.11 T11: source-induced endpoint-jet family completed; scope must remain local

User: U0033 (622780af - 97a6 - 4c56 - 987c - 135df8409461, chain 2521). **Reply:** A1206 (ea7fad65 - aa59 - 4169 - 8bbd - 5e73a631d3ae, chain 2613).

origin information: it consists of

Requested calculation. Track higher supported relation data rather than discard it.

Original objects and maps. $\varphi_j = D^j \varphi^*$, W_m, N , $I_W = (gs^m)$, $D_m = O/(gs^m)$.

Actual result and proof scope. The endpoint kernel $O/(s^m)$ embeds by $\times g$; $g(0)=1$ is computed from the actual theta boundary; Bezout coefficients give the split decomposition over a common Boolean support. Fourier supplies $s(1-s)$ with all signs.

Left uncalculated. No purity bound follows from these additional endpoint jets, and the finite subspaces are not silently D-invariant.

Exact obstruction scope. The extra endpoint factors are caused by restricting theta relations. They are not new arithmetic zeros of ξ .

Later completion or correction. A1304 builds the reflected comparison; A1361 corrects its cohomological placement; A1427 enlarges finite labels to D-saturation with its kernel.

Concrete surviving derivation. Keep the endpoint exact sequences and Fourier transport, then use the actual full two-leg source when computing A_τ . The attached all-m calculation identifies the exact realization syzygy rather than introduce another polynomial family.

230.4.12 T12: scope displacement, explicitly conceded later

User: U0034 (b5ee7e11 - a089 - 4433 - af7a - ede73bbc5bcf, chain 2614). **Reply:** A1235 (ca9499fc - 3b1b - 49a8 - 8705 - 047fc4fec20e, chain 2661).

The programme needs to return to one RH-level target: positivity of the unshifted Weil form

Requested calculation. Return to Weil II on the user's program and clarify the route.

Original objects and maps. Finite spectral-triple unshifted form QW , ε shift, finite ground-line quotient, theta truncation.

Actual result and proof scope. The reply gives genuine finite comparison formulas and sufficient lower-bound criteria.

Left uncalculated. It promotes a downstream RH-equivalent criterion to the primary task instead of completing the requested cohomology/Lefschetz/Deligne construction.

Exact obstruction scope. The positivity criterion is mathematically relevant but does not replace the requested construction over the τ -base.

Later completion or correction. A1280 explicitly states that the lower bound 'should not have displaced' cohomology, action, and duality.

Concrete surviving derivation. Resume primary $A_\tau = R\Gamma$, K_τ , Mellin-jet injection and actual tensor powers. Use positivity as a consequence to be proved for their trace, not a generic replacement deliverable.

230.4.13 T13: legitimate exact descent obstruction

User: U0034 (b5ee7e11-a089-4433-af7a-ed73bbc5bcf, chain 2614). **Reply:** A1235 (ca9499fc-3b1b-49a8-8705-047fc4fec20e, chain 2661).

the unshifted form descends through this particular quotient precisely when

Requested calculation. Carry the original quotient into the cited spectral construction.

Original objects and maps. $A, \varepsilon = \min$ eigenvalue, $B = A - \varepsilon I$, ground line $L = C_V$, quotient q .

Actual result and proof scope. $QW(f, g) = \text{Bbar}(qf, qg) + \varepsilon \langle f, g \rangle$. The unshifted form descends through E/L iff $\varepsilon = 0$; the shifted form descends, and its distribution is $\Psi - \varepsilon \delta 1$.

Left uncalculated. The missing estimate is control of the original ε term, not proof that the shifted form is positive.

Exact obstruction scope. This excludes descent through that ground-line quotient for $\varepsilon \neq 0$ only. It does not exclude all supported comparisons or all τ -base duality.

Later completion or correction. A1361 retains this exact correction instead of a blanket rejection of the finite model.

Concrete surviving derivation. Retain the direct form identity or the two terms as structured data and calculate their exact pullback along the original theta map. Do not identify the shifted positive form with the raw residue/Weil trace pairing.

230.4.14 T14: typed correspondence completed; estimate abandoned at explicit term

User: U0034 (b5ee7e11-a089-4433-af7a-ed73bbc5bcf, chain 2614). **Reply:** A1235 (ca9499fc-3b1b-49a8-8705-047fc4fec20e, chain 2661).

Those kernels are the retained discrepancy

Requested calculation. Integrate arithmetic theta relations with the finite spectral quotient.

Original objects and maps. $T = \Pi_{NP} \lambda C$, $R = T \ominus W$, $L = C_V$, common quotient $E/(R+L)$, linear relation $C_{W, \lambda, N}$.

Actual result and proof scope. Both quotient kernels $L/(L \cap R)$, $R/(R \cap L)$ are explicit; the latter is the multivalued output fibre of the theta-to-ground-line relation.

Left uncalculated. R is not computed for all original W , and the residual-to-gap term remains unestimated uniformly.

Exact obstruction scope. Failure of a single-valued map to E/L is measured by $R/(R \cap L)$; the exact correspondence survives.

Later completion or correction. A1280 restores the cohomological route; the raw finite relation can remain a diagnostic.

Concrete surviving derivation. Compute R and the unshifted form on actual theta-generated finite subspaces, retaining its kernel. Any residual estimate must include the same support relations and all endpoint terms.

230.4.15 T15: explicit incomplete calculation, not a finished bound

User: U0034 (b5ee7e11-a089-4433-af7a-ed73bbc5bcf, chain 2614). **Reply:** A1235 (ca9499fc-3b1b-49a8-8705-047fc4fec20e, chain 2661).

The uniform residual-to-gap estimate is the nontrivial term left

Requested calculation. Use Weil II to make actual progress on the arithmetic program.

Original objects and maps. $u = \Pi_P K$, v lowest eigenvector; spectral gap $g_{\lambda, N}$, theta tail and Fourier projection tail.

Actual result and proof scope. A concrete complex-strip error bound is derived with all three terms: theta tail, Fourier projection tail, and residual/gap.

Left uncalculated. No uniform estimate for $\|(A - \epsilon I)u\|/\text{gap}$ is carried out; small Rayleigh quotient controls only the upper side of the minimum.

Exact obstruction scope. The inequality locates an analytic problem; it neither proves convergence nor proves the desired lower bound.

Later completion or correction. U0035 demands calculations rather than proposals; U0036 redirects to traces and cohomology; A1280 accepts the correction.

Concrete surviving derivation. For the exact original theta source, calculate residual and boundary contributions before invoking a gap argument. Root's original-source analytic lane should supply that computation rather than this audit duplicate it.

230.4.16 T16: instruction incorporated after consecutive user steering

User: U0035 (7b9f7612 - 3a57 - 4687 - 9bfb - 39d1d933baf8, chain 2662). **Reply:** A1280 (3c7dd1ba - 95eb - 4919 - b2db - efef2948ddd1, chain 2749).

The lower bound I named is a downstream criterion

Requested calculation. Do requested mathematics rather than merely say it should be done.

Original objects and maps. User U0035 followed by U0036; no substantive assistant response between them in this retained segment.

Actual result and proof scope. A1280 acknowledges the displacement and performs convolution-action/finite-trace/endpoint-action calculations.

Left uncalculated. Its global cohomological trace and purity remain incomplete; the acknowledgement does not complete them.

Exact obstruction scope. This user directive applies to continued mathematical work, not just wording or a redo prompt.

Later completion or correction. A1304 and A1427 execute further concrete algebraic repairs.

Concrete surviving derivation. Continue actual calculations on retained A_T/K_T ; supplementary redo instructions do not satisfy the instruction by themselves.

230.4.17 T17: actual action repaired by enlargement; change of label category must stay visible

User: U0036 (d6542f7d - b917 - 4de5 - b35d - 07062f16e9c1, chain 2679). **Reply:** A1280 (3c7dd1ba - 95eb - 4919 - b2db - efef2948ddd1, chain 2749).

its source relations must be invariant

Requested calculation. Construct cohomologies and Lefschetz traces.

Original objects and maps. $Q_W = B/\Theta W$, convolution H_h , $W^A = W + \text{span}\{h^*\varphi\}$.

Actual result and proof scope. Convolution commutes with Θ , saturation is idempotent and join-compatible, and the map to invariant relations has kernel $\Theta W^A/\Theta W$.

Left uncalculated. The new saturated label is usually not finite-dimensional. It is a transition into a larger invariant-subspace category, not an endomorphism of every original finite fibre.

Exact obstruction scope. Non-invariance obstructs only the claimed fixed- W endomorphism. The saturated action and moving-label map both survive.

Later completion or correction. A1361 explicitly corrects treating saturation as another finite label. Primary (34)–(35) supplies the full two-leg action without a label substitution.

Concrete surviving derivation. Use $(U_a, aU_1/a)$ on $V \oplus V$ and U_a on B . For finite subspaces keep either the moving label or the explicit saturation kernel, and retain the original absent-leg masks.

230.4.18 T18: finite trace and arithmetic distribution completed; global trace not established

User: U0036 (d6542f7d - b917 - 4de5 - b35d - 07062f16e9c1, chain 2679). **Reply:** A1280 (3c7dd1ba - 95eb - 4919 - b2db - efeb2948ddd1, chain 2749).

not asserted to be an ordinary trace of every infinite semimodule quotient

Requested calculation. Apply cohomological Lefschetz machinery to the original object.

Original objects and maps. Finite A_Z , multiplication by Mellin h , E_0/E_1 moment lines, spectral sum, prime and archimedean distribution.

Actual result and proof scope. The full-jet multiplication trace is $\sum m_\rho Mh(\rho)$; moment actions give $Mh(0)$, $Mh(1)$; compact smooth test decay gives the stated spectral distribution, using the cited explicit formula.

Left uncalculated. The reply does not prove that this distribution is an ordinary/nuclear trace on the full supported theta quotient or calculate a global realization kernel contribution. E_0/E_1 are not yet constructed as geometric cohomological degrees 0 and 2.

Exact obstruction scope. All finite traces may be correct while the infinite cohomological trace identification still requires a topology and exact trace theorem.

Later completion or correction. A1361 records this gap explicitly; primary (43) retains an algebraic dual map and deliberately avoids asserting continuous/global duality.

Concrete surviving derivation. Specify and prove continuity/nuclearity or a regularized trace construction on the original strong-Schwartz quotient, track the realization kernel, and preserve all prime, gamma, moment, and boundary terms.

230.4.19 T19: response to consecutive U0037/U0038; actual algebra executed, Deligne application overstated

User: U0037 (8b2110e7 - 195b - 42d0 - 8c86 - 7277004e35fd, chain 2750). **Reply:** A1304 (7fd7ecd5 - 0f3d - 4673 - 94dc - 9cda82bee9ed, chain 2801).

The concrete application is a

Requested calculation. Apply the requested machinery to the program.

Original objects and maps. Original mixed double $G(R)^2$, all three masks, $d_m = (gs^m p(a) - g(1-s)^m p(b))$, c_m .

Actual result and proof scope. The three support fibres, endpoint transport kernels, joint cycles, and analytic image are computed using explicit Bezout coefficients and actual differentiated theta inputs.

Left uncalculated. The analytic realization creates relations and changes cohomology; that effect is not carried through here. The reply does not construct the global Deligne comparison.

Exact obstruction scope. These are valid source-induced local algebraic calculations. They are not a proof of weight bounds for the global original construction.

Later completion or correction. A1361 identifies the raw syzygy and image-versus-cohomology issue; A1427 supplies operator balancing and corrects the claim of applying Deligne.

Concrete surviving derivation. Retain the d_m comparison as an analytic image of actual theta source subcomplexes, with the exact comparison cone. The attached all- m proof computes that map and its support faces.

230.4.20 T20: perfect residue duality calculated; transfer to right adjoint not yet present here

User: U0038 (4ab2ff8f-915a-417d-876f-7294ed662b24, chain 2753). **Reply:** A1304 (7fd7ecd5-0f3d-4673-94dc-9cda82bee9ed, chain 2801).

Now use the duality operation needed by the Deligne route

Requested calculation. Use both Deligne and split zero in the actual program.

Original objects and maps. $C_m \rightarrow O_m$, finite reflected packets, $\text{Ext}_1(-, R \text{ ds})$, $R_m, \mathbb{Z}$, L_1 action.

Actual result and proof scope. The residue pairing is perfect, $\text{im } c_m = (\ker c_m)^\perp$, endpoint jets have the displayed anti-diagonal signs, and covariance has factor a .

Left uncalculated. A local Ext residue pairing is not yet identified with the right adjoint of the program's global pushforward in this episode.

Exact obstruction scope. Perfect duality and weight-one covariance alone do not imply positivity. This is a limited obstruction, not program failure.

Later completion or correction. A1361 proves skew-Hermitian orientation and formal counterexample; the primary (26)–(43) later computes $K\tau$ and gives an explicit injection into its algebraic dual.

Concrete surviving derivation. Use primary (43) to place this finite residue duality in $\text{RHom}(T, K\tau(L_1))$; carry its continuous/topological status separately and calculate its arithmetic estimate.

230.4.21 T21: trace contraction completed; full nilpotents retained before contraction

User: U0038 (4ab2ff8f-915a-417d-876f-7294ed662b24, chain 2753). **Reply:** A1304 (7fd7ecd5-0f3d-4673-94dc-9cda82bee9ed, chain 2801).

specific morphism whose pairing is the actual finite Weil spectral pairing

Requested calculation. Connect the actual duality and arithmetic trace.

Original objects and maps. $J_g = [\times g']$, $P_m = [\times (1-s)^m g']$, raw residue R_Z , trace Q_Z .

Actual result and proof scope. $R_Z(f, J_g h) = \sum m \rho \text{conjugate}(f(\iota \rho)) h(\rho) = \text{Tr } M_f \uparrow h$; at multiplicity r , J_g has kernel (z) and image (z^{r-1}) .

Left uncalculated. The finite trace contraction is not an estimate, and the radical does not prove supported jet fibres are absent.

Exact obstruction scope. Scalar trace forgets nilpotent off-diagonal data through an explicit endomorphism. The perfect residue pairing still sees it.

Later completion or correction. A1361 keeps the orientation and generator-change factors; primary (42)–(45) integrates this same operation.

Concrete surviving derivation. Carry R_Z and J_g as distinct typed maps into $K\tau$, preserving $g=2$ ξ and the full unit $u_\rho(z)$. Use the trace contraction only for the observable it computes.

230.4.22 T22: legitimate narrow obstruction, explicit scope retained

User: U0039 (71c1d5ee-668e-4eea-ac21-d844702248ea, chain 2802). **Reply:** A1361 (c9e551ee-298f-438b-9bdc-2e23c2c0613a, chain 2922).

It does not, by itself, prove that this final kernel is nonzero.

Requested calculation. Audit and repair roughly 25 turns without normalizing or terminating a lane.

Original objects and maps. Raw $\delta: O^2 \rightarrow O \otimes B$ from $b+ = \Theta D\varphi$, $b- = \Theta(1-D)\varphi$, β evaluation.

Actual result and proof scope. δ is injective while $\ker \beta\delta = O(1-s, s)$; $z = (1-s) \otimes b+ - s \otimes b-$ is nonzero and maps to zero. For the full source z lies in $\delta \ker \alpha$ and therefore does not prove the final H1 kernel nonzero.

Left uncalculated. The full raw H1 kernel remains unresolved at this point.

Exact obstruction scope. The obstruction excludes the raw restricted comparison being a quasi-isomorphism. It does not establish no other realization or no τ -base program.

Later completion or correction. A1427 proves raw H1 kernel nonzero by a different argument and identifies z as an operator-balancing relation.

Concrete surviving derivation. Keep both calculations and their distinct scopes. The attached all-order proof extends z to every $m \geq 1$ without changing masks or g .

230.4.23 T23: corrected cohomological placement

User: U0039 (71c1d5ee-668e-4eea-ac21-d844702248ea, chain 2802). **Reply:** A1361 (c9e551ee-298f-438b-9bdc-2e23c2c0613a, chain 2922).

is **the image**, not either cohomology group.

Requested calculation. Make all preceding work self-consistent.

Original objects and maps. Two-term $[C_m \rightarrow O_m]$, kernel $E_{0,m}$, image I , cokernel $E_{1,m}$.

Actual result and proof scope. $H_0 = E_{0,m}$, $H_1 = E_{1,m}$; I is the comparison image and cancels from this complex's supertrace. Dilation supertrace is $m(1-a)$.

Left uncalculated. No actual global comparison producing I as a middle image with both bounds is constructed in this episode.

Exact obstruction scope. A correct kernel-image-cokernel exact sequence cannot be relabelled as $H_1 = I$.

Later completion or correction. Primary (21)–(22) really has $H_1 = Q$ and (39) induces $Q \rightarrow A_Z$; this is the strongest later exact cohomological placement.

Concrete surviving derivation. Retain the two endpoint short exact sequences as data over A_τ , then use the actual Q cohomology for the spectral packet map. Never take the arithmetic trace of I as the supertrace of $[C_m \rightarrow O_m]$.

230.4.24 T24: legitimate formal counterexample; no failure verdict for original arithmetic program

User: U0039 (71c1d5ee-668e-4eea-ac21-d844702248ea, chain 2802). **Reply:** A1361 (c9e551ee-298f-438b-9bdc-2e23c2c0613a, chain 2922).

perfect duality and weight-one covariance alone do not force positivity

Requested calculation. Give exact scope and constructive successor for every obstruction.

Original objects and maps. Actual raw R_Z, J_g ; auxiliary $g_0=(s-1/4)(s-3/4)$, $U=\text{diag}(2,8)$.

Actual result and proof scope. The auxiliary model has R skew-Hermitian, $Q=RJ=[0,1],[1,0]$, $U*QU=16Q$ and negative value on $(1,-1)$.

Left uncalculated. It does not compute the additional arithmetic property of the actual theta image which would exclude such a pairing.

Exact obstruction scope. Only the universal implication ‘perfect residue duality plus covariance implies positivity’ fails. ξ , its theta source, and τ -base $A\tau/K\tau$ have not been disproved.

Later completion or correction. A1427 explicitly retains richer arithmetic geometry as the continuing route; primary (50) states the actual unproved tensor defect.

Concrete surviving derivation. Use the counterexample as a mutation control on any proposed proof, then calculate the original theta relation estimates. Do not replace ξ by this auxiliary polynomial as the main research object.

230.4.25 T25: actual supported discrepancy completed

User: U0039 (71c1d5ee-668e-4eea-ac21-d844702248ea, chain 2802). **Reply:** A1361 (c9e551ee-298f-438b-9bdc-2e23c2c0613a, chain 2922).

the two Frobenius operations differ

Requested calculation. Carry exact maps when operations cannot be identified.

Original objects and maps. Φ_q additive Frobenius lift and $P_q=x*q$ in $D_{A,n}$; $A=F_5, n=3, x=(1,1, \tau)$.

Actual result and proof scope. $\Phi_5(x)=(1,\tau,4)$, $x*5=(1,e,4)$; $\pi\Phi_q=F_q\pi=\pi P_q$ and (P_q, Φ_q) maps to the arithmetic fibre product in pointed multiplicative monoids.

Left uncalculated. No global Frobenius action on the richer arithmetic cohomology is built from that coefficient comparison.

Exact obstruction scope. The two supported operations differ; they remain explicitly related over the arithmetic quotient. Finite étale amplitude purity cannot be assigned to both.

Later completion or correction. A1427 supplies a root-cover coefficient square but carefully limits its geometric claims.

Concrete surviving derivation. Keep the fibre-product comparison when using finite-characteristic coefficients, while retaining the actual characteristic-zero scaling action on $A\tau$. Do not conflate the two.

230.4.26 T26: verification overstatement found and repaired

User: U0039 (71c1d5ee-668e-4eea-ac21-d844702248ea, chain 2802). **Reply:** A1361 (c9e551ee-298f-438b-9bdc-2e23c2c0613a, chain 2922).

identical normal and optimized output demonstrated equivalent checking was not justified

Requested calculation. Audit rigor and prior calculations.

Original objects and maps. Two prior checkers, 33 assert sites, normal/optimized executions.

Actual result and proof scope. The transcript reports hardened copies and deliberate failing guards in both modes.

Left uncalculated. Passing finite checks remains distinct from proof of the analytic/global claims; this audit has not independently rerun those old packages.

Exact obstruction scope. The defect concerns the optimized checker claim, not all mathematical formulas in those packages.

Later completion or correction. Root has an independent current-audit replay lane; this segment audit intentionally does not duplicate it.

Concrete surviving derivation. Preserve source hashes and use explicit exception/mutation controls for new computational checks; cite full written arguments for infinite analytic statements.

230.4.27 T27: requested F1 morphisms substantially supplied

User: U0040 (a10456e9-7f72-4c81-bc00-118fcd575269, chain 2923). **Reply:** A1427 (d7e752ce-cb39-4130-b089-b20333037990, chain 3056).

The full square is the object to retain

Requested calculation. Supply exact maps, audit Deligne reading, check globalization primality and F1 connection.

Original objects and maps. $P\tau \subset P0 \subset Pp$, p_R , Spec inclusions, $B_{bare} \rightarrow B_R$, contracted monoid ring, Boolean nonunital section.

Actual result and proof scope. The two primality statements, arithmetic closed subspace $V(e)$, distinct generic localizations, blueprint completion/recovery, nonunital Boolean retraction, and all-rank monomial automorphism sequence are explicitly connected.

Left uncalculated. No literal six-item specification was located, so certification against all six was not performed. This is an acquisition/specification limit, not evidence the F1 program fails.

Exact obstruction scope. Unital Boolean inclusion failure only requires retaining the nonunital idempotent retraction or genuine pointed blueprint base. It does not erase the absolute base.

Later completion or correction. Primary (1)–(8) constructs $F1, \tau$ and structural map to $b\tau$; canonical route proves $B \otimes_G(R)M \cong eM$ alongside, not instead of, $A\tau$.

Concrete surviving derivation. Use the actual structural blueprint morphism and cohomological pushforward. Never substitute the generic σ Boolean stalk for the τ -base or claim the source omitted (0).

230.4.28 T28: raw-kernel nonvanishing completed; balanced successor only partly calculated

User: U0040 (a10456e9-7f72-4c81-bc00-118fcd575269, chain 2923). **Reply:** A1427 (d7e752ce-cb39-4130-b089-b20333037990, chain 3056).

The raw tensor realization really does have a nonzero kernel.

Requested calculation. Replace every nonidentity warning with a typed map and continuation.

Original objects and maps. $Q = B/\Theta V$, raw $0 \otimes C Q \rightarrow 0/(g)$, $g=2\xi$; balanced $0 \otimes C[t]Q$.

Actual result and proof scope. The nonzero free raw source contains $g(0 \otimes Q)$ in the kernel. Operator balancing imposes $sh \otimes v - h \otimes Dv$, factors the raw map and kills the earlier explicit z .

Left uncalculated. K_{bal}^1 is still not computed globally. The nonzero raw kernel argument does not apply automatically after balancing.

Exact obstruction scope. The raw scalar extension is not faithful to the torsion divisor realization. This excludes that raw map being an isomorphism, while the operator-balanced route survives.

Later completion or correction. Primary (39),(43) gives actual finite quotients and dual injections without assuming either global realization is an isomorphism.

Concrete surviving derivation. Compute K_{bal} on the original module with its topology and action. The attached explicit free finite-packet embedding makes the raw-kernel theorem constructive and preserves every finite jet.

230.4.29 T29: finite realization completed; finite-to-global extrapolation forbidden

User: U0040 (a10456e9-7f72-4c81-bc00-118fcd575269, chain 2923). **Reply:** A1427 (d7e752ce-cb39-4130-b089-b20333037990, chain 3056).

The finite-jet realization is now an actual isomorphism

Requested calculation. Construct the missing typed morphisms.

Original objects and maps. $A = C[t]$, $Q_{\rho,m} = A/(t-\rho)^m$, $0 \otimes A Q_{\rho,m} \rightarrow 0/(s-\rho)^m$.

Actual result and proof scope. $h \otimes P \mapsto hP(s)$ has inverse $[h] \mapsto h \otimes 1$; 0 is torsion-free over PID A and flat. The single-source complex $[0 \otimes A V \rightarrow 0 \otimes A B]$ has $H_0 = 0$.

Left uncalculated. The complete Q is not proved to be the direct sum/limit of these finite jet modules with an appropriate topology. Its balanced realization kernel remains.

Exact obstruction scope. Matching every finite jet does not prove global quasi-isomorphism. The single-source $H_0 = 0$ must not replace the actual joint $A\tau$ complex, whose $H_0 = V$.

Later completion or correction. Primary (21)–(22),(38)–(43) preserves this distinction and uses finite packet maps with exact scope.

Concrete surviving derivation. Retain the honest joint H_0 and all support masks. The attached saturated two-leg calculation proves its surviving syzygy explicitly rather than declaring all H_0 removed by balancing.

230.4.30 T30: accurate application limit; source audit delivered, missing geometry not calculated

User: U0040 (a10456e9-7f72-4c81-bc00-118fcd575269, chain 2923). **Reply:** A1427 (d7e752ce-cb39-4130-b089-b20333037990, chain 3056).

A verified application of its purity theorem to the full split-support arithmetic object was not constructed.

Requested calculation. Audit what Deligne was actually read and push the object through the method.

Original objects and maps. Recorded Weil II windows, local root covers $G(A) \rightarrow G(B)$, tame coefficient maps, analytic c_m , intended global cohomological comparison.

Actual result and proof scope. The reply distinguishes actual fresh windows from earlier reading claims, and constructs the coefficient square with supported residue zeros and commuting root-of-unity automorphisms.

Left uncalculated. The square does not construct tame lisse sheaves with the required weights or the global arithmetic $f! \rightarrow f^*$. Calling local analytic c_m an application of Deligne had been too strong.

Exact obstruction scope. The theorem's hypotheses are not established for that local comparison. This does not disprove an analogous τ -base argument; the later primary explicitly computes its own $A\tau$ and $K\tau$.

Later completion or correction. Use the later complete primary as the present starting point, so 'construct a right adjoint' is no longer left as a generic demand.

Concrete surviving derivation. Continue the exact original A_T/K_T method: prove the analytic bound on its theta-source relations and calculate all boundary/kernel terms. Keep Deligne's original argument as a method to reproduce, not a theorem whose hypotheses may be assumed.

230.5 Completed work delivered with this audit

COMPLETED_MELLIN_CALCULATIONS.md proves the raw two-leg syzygy for every original differentiated-theta order $m \geq 1$, retains each mask, supplies the exact operator-balancing relation, and calculates the honest cycles in the saturated original two-leg source. It also uses the actual smooth full-jet right inverse to inject a free rank- $\Sigma m\rho$ module into the raw Mellin-realization kernel. These results neither assume vanishing of the balanced kernel nor replace the theta source.

source_maps/VERIFIED_SOURCE_MAPS.md proves the exact structural/base-restriction relation, A_T and K_T maps, all-support versus categorical kernels, and the opposite dual-index arrows. It additionally gives the explicit equivariant factorization $A_\rho \rightarrow E \rightarrow A_\rho$ of J_g , with the retained coefficient $m\rho u_\rho(0)$ and the actual socle eigenline inside the full nilpotent packet.

230.6 Prioritized continuation for integration

1. Integrate the later primary A_T/K_T construction into the historical findings first. The missing right adjoint and finite residue-to-dual arrow are now completed; no generic-stalk substitute is needed.
2. Carry the raw and operator-balanced Mellin maps as separate exact comparisons. The raw kernel is provably nonzero; the balanced kernel requires actual calculation on Q with its topology and action. The attached all-order calculations give explicit subcomplexes and kernel elements.
3. Calculate the original theta relation estimates with all boundary terms, masses, Fourier/scaling factors, and the retained unshifted trace correction. The unproved uniform residual/gap term and unsupported norm transfer are identifiable interruptions, not complete results.
4. Establish the trace on a specified infinite arithmetic realization and account for its kernel/cone contribution. Finite full-jet traces and an absolutely convergent spectral distribution alone do not provide that theorem.
5. Retain valid obstructions at their exact scope: pointed-section nonsplitting, filtered-map non-strictness, unshifted-form descent, raw realization non-quasi-isomorphism, and formal covariance without positivity. Each has an explicit surviving map in this ledger. None proves failure of the entire τ -base program.

These are integration priorities for the original program. They are not conditional theorems in which a missing bound or vanishing is assumed.

231 Actual tau cohomology: U0041–U0054

232 Passage audit: actual tau cohomology and continuation, U0041–U0054

The entire 7,811-line segment and complete primary Tau Base NOTE were read. The current segment SHA-256 is e79b46722d9a2ee95b68ae6512f37a19fd41e4b3ecc4e53583cd357d0442c251. All 14 user inputs, progress responses and substantive answers are represented below. The extraction owner’s newline-only repair preserves the UUID locators and exact quotations. The full user text is preserved in the JSON and separate provenance file.

The accepted original construction is A1523, explicitly accepted by U0046. The concrete A1545 promise to calculate the full reversed-support dual is completed in FULL_SUPPORT_DUAL.md/.tex with its standalone retraction supplement. The repeated remaining quantitative endpoint is the uniform arithmetic control, not a missing definition of A_{tau} or K_{tau} .

232.1 AT41: U0041 → A1458

User node b85d7358 - ede3 - 4c0e - ab3f - 45b067391b12, chain 3057, source line 1. Completed literal support propagation; arithmetic transfer not computed.

Retained turns: U0041 (b85d7358 - ede3 - 4c0e - ab3f - 45b067391b12), A1429 (0db9d22c - 28a2 - 4f93 - a2f8 - fd09c4ecb11d), A1458 (5ae3c5b9 - 7f5c - 46a6 - 92c6 - 09933220f7aa).

Exact passage, U0041 node b85d7358 - ede3 - 4c0e - ab3f - 45b067391b12, line 3:

Try to get hardcore typed morphisms without simplification that you propagate through each and every equation, while tracking the interesting bits continually.

Exact passage, A1458 node 5ae3c5b9 - 7f5c - 46a6 - 92c6 - 09933220f7aa, line 818:

No equivalence between that entire analytic complex and the geometric complexes above is asserted here.

Requested calculation. Carry the original infinite quotient and split support through the stated Deligne operations by exact typed maps.

Actually proved. The answer constructs the marked geometry $(\widehat{X}, \mathcal{S}_X, \mathbf{p}_X)$, its induced site, support diagrams and original coequalizer cohomology. It retains $G(\mathcal{O}_K) \rightarrow \mathcal{O}_K$, the closed arithmetic subspace $V(e)$, the cycle formula for support-comparison kernels, extension by absence versus the retained boundary skeleton, dual precomposition, all tensor signs and the e -seeded Lefschetz sum, including an empty fixed-point set. Its finite-field comparison image is proved under Deligne’s explicitly stated smooth/lisse/pure hypotheses; its final support projection kernel is not set to zero.

Left uncalculated. No source-sensitive morphism transfers the finite-field weight estimates to the original characteristic-zero theta cohomology. The retained map $\mathcal{O} \otimes_{\mathbb{C}[t]} Q \rightarrow \mathcal{O}/(2\xi)$ is not proved to be an equivalence to the finite-field comparison complexes.

Exact obstruction scope. The finite-field theorem is a legitimate scoped calculation, not a proof or disproof of the original absolute-base program. No kernel vanishing or broad nonrelationship is proved.

Later completion. U0043 rejects stopping at a finite-field lift; A1523 constructs the actual absolute-base $A_{\text{tau}}/K_{\text{tau}}$ system.

Concrete continuation. Retain these support operations but resume A1523’s accepted absolute-base theta cohomology; do not repeat a renamed finite-field theorem.

232.2 AT42: U0042 → A1474

User node 40ac47e6-d648-406d-91e5-085f3e6ecb67, chain 3130, source line 822. Completed finite-packet nullity and signature calculation; absolute-base estimate remains.

Retained turns: U0042 (40ac47e6-d648-406d-91e5-085f3e6ecb67), A1474 (32b7efb8-d9e3-4f15-9dd5-e15827f2241d).

Exact passage, A1474 node 32b7efb8-d9e3-4f15-9dd5-e15827f2241d, line 1136:

This is a **newly stated test of a particular trace-theoretic relation**, not a redefinition of your existing quotient.

Exact passage, A1474 node 32b7efb8-d9e3-4f15-9dd5-e15827f2241d, line 1267:

The sharpened question is whether the arithmetic e -null fibre is a radical through which the pairing descends.

Requested calculation. Determine the individual mathematical roles of tau and e in testing the arithmetic pairing and RH.

Actually proved. The response proves pairing descent exactly when its restricted map to the dual vanishes. For the actual packet it computes

$$Q_Z(f, h) = \sum_{\rho} m_{\rho} \overline{f(1 - \bar{\rho})} h(\rho), \quad \text{Rad } Q_Z = \{f : f(\rho) = 0 \forall \rho\}.$$

It retains all local units in the full residue pairing, gives its Jacobian contraction to this trace form, and calculates every off-line reflected block's isotropic coordinate vectors, nonzero cross pairing and positive/negative signature. The trace radical quotient legitimately forgets nilpotent amplitudes while retaining zeros and multiplicities. Synchronization preserves the arithmetic amplitude and hence cannot erase a diagnostic value.

Left uncalculated. The finite nullity criterion is not the cohomological arithmetic argument forcing positivity or radicality. No absolute-base weight estimate is calculated.

Exact obstruction scope. Failure of a proposed self-null congruence is an exact obstruction to that quotient, not to the already valid original coequalizer or the whole tau-base program. A negative auxiliary finite model is not an RH counterexample.

Later completion. A1523 supplies the original-base adjoint and residue injection; A1644 supplies the arithmetic extension unit and equivariant finite trace.

Concrete continuation. Use the computed residue/Jacobian map in the actual A_{τ}/K_{τ} continuation. Prove the analytic control of that image; do not replace it by the already established RH criterion.

232.3 AT43: U0043 → A1523

User node d908924e-830b-46ad-8d9c-f2b78a536989, chain 3157, source line 1271. Requested change to absolute tau base completed and accepted.

Retained turns: U0043 (d908924e-830b-46ad-8d9c-f2b78a536989), U0044 (457e7cf8-ce51-4d20-afe4-e998185d2e17), U0045 (c7241c17-6d01-4d7f-bd87-78977a059471), A1481 (5d7a3844-3f4c-4652-a5d9-cd4d586e4c75), A1520 (3f9d0b49-19dc-44cc-87a7-f139138cd6b9), A1523 (b670b6c0-a774-4398-b978-9c9779fca379).

Exact passage, U0043 node d908924e-830b-46ad-8d9c-f2b78a536989, line 1273:

and then use his machinery instead over the other thing, like tau instead of E, which was the intent, for the record. That's what I wanted you to do.

Exact passage, A1523 node b670b6c0 - a774 - 4398 - b978 - 9c9779fca379 , line 1957:

The construction uses the structural morphism a_R , keeping p_R attached. It does not replace the arithmetic object by its Boolean localization.

Exact passage, A1523 node b670b6c0 - a774 - 4398 - b978 - 9c9779fca379 , line 2478:

The remaining issue is **a weight or positivity theorem for this new-base arithmetic realization**.

Requested calculation. Change the actual base to tau, instead of repeating the finite-field theorem with split notation, and perform the Deligne-like constructions on that object.

Actually proved. A1520 first supplies a pointed-monoidal structural map, the mixed-boundary contraction with stalk $G(A)^2 \rightarrow A^2$, and boundary cohomology Q^2 , retaining mixed multiplication and synchronization. Its product is expressly topological, not asserted to be the universal semiring-scheme product. A1523 then gives the canonical retained blueprint construction: the structural map $F_{1,\tau} \rightarrow B_R$, four-point original theta chart, projective resolution computing $A_\tau = R\Gamma(P, -)$, separate restriction to sigma with its chain homotopy, signed right-adjoint complex $K_\tau(W) \simeq S_\eta W[1]$, and full reversed precomposition arrows. It retains the source actions $U_a, aU_{1/a}$, the arithmetic weight-one moment line, all Mellin jets and the residue injection into the computed K_tau dual. It proves top tensor cohomology $Q^{\otimes r}$, product adjoint, and exact finite-packet deletion cone and trace.

Left uncalculated. No weight estimate is proved from the tensor action alone. An involutive global Verdier duality and prime-sensitive Lefschetz geometry are not constructed merely by the structural map.

Exact obstruction scope. The direct image A_τ is not Boolean generic restriction. Its explicitly compared restriction retains the labelled support skeleton while the global Q classes survive. The single-active-fibre lemma about mapping a supported vector to tau does not apply unchanged to arbitrary nonzero-bottom semimodules. A1520's Q^2 is the pushforward of two pulled-back coefficient copies at a contracted boundary; A1523's Q is the original joint chart's global cohomology. They are different declared functors, not contradictory values of one functor.

Later completion. U0046 expressly says this is now the correct context and orders continuation using these objects. A1644-A1959 genuinely continue the original theta source; no whole-program failure is established in this segment.

Concrete continuation. Resume canonical A1523/retained NOTE objects, preserving its comparison to sigma and all supports. Complete the original arithmetic estimate, not a generic-stalk replacement or an unrelated polynomial family.

232.4 AT44: U0044 $\rightarrow$ A1523

User node 457e7cf8 - ce51 - 4d20 - afe4 - e998185d2e17 , chain 3159, source line 1275. Reinforcement of U0043; completed by shared A1523 response.

Retained turns: U0044 (457e7cf8 - ce51 - 4d20 - afe4 - e998185d2e17) .

Exact passage, U0044 node 457e7cf8 - ce51 - 4d20 - afe4 - e998185d2e17 , line 1277:

which is thus what you will in fact do

Requested calculation. Carry out the absolute-tau-base construction ordered in U0043.

Actually proved. This has no separate assistant response before U0045. The complete shared response is audited at AT43.

Left uncalculated. Same subsequent arithmetic estimate as AT43; no additional mathematical calculation is introduced by this reinforcement.

Exact obstruction scope. Do not invent a separate abandoned episode from adjacent user reinforcement.

Later completion. A1520 and A1523 supply the construction, followed by explicit user acceptance U0046.

Concrete continuation. Use AT43 continuation, retaining this input in provenance.

232.5 AT45: U0045 → A1523

User node c7241c17-6d01-4d7f-bd87-78977a059471, chain 3161, source line 1279. Urgency reinforcement of U0043; completed by shared A1523 response.

Retained turns: U0045 (c7241c17-6d01-4d7f-bd87-78977a059471) .

Exact passage, U0045 node c7241c17-6d01-4d7f-bd87-78977a059471, line 1281:

nnow

Requested calculation. Execute the already ordered absolute-base construction immediately.

Actually proved. A1481 progress and A1520/A1523 are the shared response; their mathematics is audited at AT43.

Left uncalculated. Same later quantitative estimate as AT43.

Exact obstruction scope. No new mathematical hypothesis or alternative construction is requested.

Later completion. U0046 explicitly accepts A1523's context.

Concrete continuation. Use AT43 continuation, retaining this input in provenance.

232.6 AT46: U0046 → progress responses

User node 0af0ed52-c7ab-45fb-85a5-1911193398cb, chain 3260, source line 2482. Progress-only interval; explicit full reversed-support dual promise completed by this audit.

Retained turns: U0046 (0af0ed52-c7ab-45fb-85a5-1911193398cb), A1525 (d07bf9b2-4bbf-4450-b206-9df18980b10d), A1533 (48573948-14de-4d6d-a29b-2e291b816c22), A1545 (bacc895-0427-42ee-b6f6-4c61752dfde2) .

Exact passage, U0046 node 0af0ed52-c7ab-45fb-85a5-1911193398cb, line 2484:

you started on the DELINGE program in the correct context nowadays

Exact passage, U0046 node 0af0ed52-c7ab-45fb-85a5-1911193398cb, line 2484:

continue using the objects as the results so far allo

Exact passage, A1525 node d07bf9b2-4bbf-4450-b206-9df18980b10d, line 2488:

then I'll extend the comparison kernel while retaining e , τ , and support transports.

Exact passage, A1545 node bacc895-0427-42ee-b6f6-4c61752dfde2, line 2496:

including bottom fibers created by reversed support arrows.

Requested calculation. Publish the existing work as GitHub merge requests and continue the now-accepted original tau-base program using the constructed objects.

Actually proved. The retained assistant responses are progress messages about integration and continuation. No substantive final mathematical calculation intervenes before U0047 'cont'. A1545 specifically promises the full tau-chart dual, including bottom fibres created by reversing support arrows.

Left uncalculated. The full L^{op} cohomology diagram and its nonzero new bottom fibre are not written in this interval. Later A1644/A1694 retain joint H0 and single-fibre duals but do not explicitly complete the whole reversed diagram.

Exact obstruction scope. This is a precise deferred mathematical promise, not evidence about motives. Historical PR status in these messages is not independently verified remote state in this lane.

Later completion. Completed here in FULL_SUPPORT_DUAL.md/.tex, with a full standalone retraction supplement.

Concrete continuation. Use the completed explicit complexes and precomposition maps: $H^{-1} = Q^{\vee}$ on all active faces and $H^0 = V^{\vee}$ on the original joint mask, now the bottom. Retain the strict-natural-section obstruction, its actual surviving derived roof, and the action defect $d_a(c) = -a^w c \mathcal{F}^{-1} k_{1/a}$. Do not impose zero bottom fibres.

232.7 AT47: U0047 → A1644

User node b6dc9d48-0230-480b-8688-c4532c9a9796, chain 3344, source line 2498. Completed original theta extension, support-coherent homotopy and finite cochain trace.

Retained turns: U0047 (b6dc9d48-0230-480b-8688-c4532c9a9796), A1580 (ee1160cc-4814-4d26-9f63-5802e7202b95), A1600 (dc3d2a73-4433-4fb7-b21d-1b912836fa18), A1601 (4071829e-6607-477c-970f-6b4149337366), A1644 (d448b4f7-00f5-449f-a2b0-43ebd22cc66f).

Exact passage, A1600 node dc3d2a73-4433-4fb7-b21d-1b912836fa18, line 2508:

Next I'm computing its compact-support-to-ordinary cohomology map.

Exact passage, A1601 node 4071829e-6607-477c-970f-6b4149337366, line 2512:

although it vanishes in cohomology, its extension class remains part of the comparison.

Exact passage, A1644 node d448b4f7-00f5-449f-a2b0-43ebd22cc66f, line 3015:

They do not yet establish the global weight estimate.

Requested calculation. Continue the accepted $A_{\text{tau}}/K_{\text{tau}}$ construction and its original comparison.

Actually proved. The response retains $C_+ = [V \rightarrow \mathcal{B}]$, the full joint comparison, original $D = -x\partial_x$, Gaussian source and $g = 2\xi$. The actual section uses the full arithmetic unit $\varepsilon_Z = j_{h_Z}(h_Z/g)$. It computes the theta extension class, polynomial-action defect, rank-one infinitesimal boundary and full dilation cocycle. At a simple zero the coefficient is exactly $1/(2\xi'(\rho))$. The two homotopies differ by the retained joint H0 cycle $(b, \widehat{b})$; synchronization supplies a common supported target without killing it. The same unit enters residue duality and the Jacobian trace. The non-A-linear section is replaced by the strict equivariant roof $E_Z[-1] \leftarrow C_Z \rightarrow C_+$. The finite-rank cochain trace keeps its degree-one minus sign and every tensor sign.

Left uncalculated. The global topological section, continuous-dual splitting and quantitative estimate are not yet supplied here. A finite packet roof is not by itself every missing prime-sensitive compact-support theorem.

Exact obstruction scope. A nonzero extension obstructs a strict equivariant representative section, not the displayed equivariant derived inclusion. The exact one-leg-to-joint comparison is present in the primary dependency and fully calculated again in the later-control supplement; its H1 map is identity and its complementary $V[0]$ survives.

Later completion. A1694 completes the global continuous section, transpose and completed tensor contractions. A1771 later computes the complete homotopy family.

Concrete continuation. Retain the extension unit and actual roof through the global control calculation. Do not drop its boundary pairings or treat focus on C_+ as deletion of the joint H0 complement.

232.8 AT48: U0048 $\rightarrow$ A1694

User node 29b1576a-8ac7-421a-8b66-cbd70eea994d, chain 3469, source line 3017. Completed global analytic retraction and Hausdorff-kernel calculation; full quantitative boundary estimate remains.

Retained turns: U0048 (29b1576a-8ac7-421a-8b66-cbd70eea994d), A1694 (1fa0ebbc-f569-40c1-b7ac-b523da19a5f0).

Exact passage, A1694 node 1fa0ebbc-f569-40c1-b7ac-b523da19a5f0, line 3287:

Their kernels are not identified with the now-vanishing Hausdorff-comparison kernel.

Exact passage, A1694 node 1fa0ebbc-f569-40c1-b7ac-b523da19a5f0, line 3575:

All three boundary and cross-pairing terms remain.

Exact passage, A1694 node 1fa0ebbc-f569-40c1-b7ac-b523da19a5f0, line 3592:

No global positivity or purity conclusion is being claimed from the retraction alone.

Requested calculation. Continue pushing the original theta program.

Actually proved. A1694 constructs the continuous left inverse $\Lambda : \mathcal{B} \rightarrow V$ using the original $\frac{1}{2} \sum \mu(n)F(n|x|)$, both Fourier-related exterior regions, fixed cutoff operator $T = A_\alpha B_\beta$, the retained inverse bound $1/(1 - \|T\|)$, and both original moments. It proves Schwartz regularity and $\Lambda\Theta = 1$, hence closed theta image, Hausdorff Q, the section s , and $\mathcal{B} \cong V \oplus Q$. It retains the different spectral and balanced analytic kernels and the exact smaller-source sequence with V/W . The full global cocycle $k_a = \Lambda U_a s$, change-of-section coboundary, old extension unit and trace are preserved. Transposition supplies continuous duals; completed tensor contractions retain all signs and joint degree-zero terms.

Left uncalculated. The full boundary expression

$$\mathcal{H}_s(\overline{U}_a u, \overline{U}_a v) - a\mathcal{H}_s(u, v) = -\langle U_a s u, \Theta k_a v \rangle - \langle \Theta k_a u, U_a s v \rangle + \langle \Theta k_a u, \Theta k_a v \rangle$$

is computed but not bounded uniformly. The auxiliary positive form is not the arithmetic Weil form. Closedness of Theta V in the original Frechet topology does not prove vanishing of the remaining spectral or balanced analytic kernels.

Exact obstruction scope. This is a real global analytic proof and a specific vanishing comparison kernel. Neither a uniform cutoff gap for changing cutoffs nor vanishing Hilbert pairing of theta boundaries is asserted. No purity follows from the global section alone.

Later completion. A1721 expands cutoff/Fourier/moment commutators and creates source matrices. A1771-A1959 further refine the original arithmetic control; none completes uniform sublinear tensor excess within this segment.

Concrete continuation. Use those later canonical representatives and retain all cross terms and inverse conditioning. The standalone RETRACTION_PROOF.md now supplies the exact Lambda used by the full-support dual completion.

233 U0049-U0054: complete later-control audit

234 Later control continuation audit: U0049-U0054

234.1 Scope, coverage and source pins

This bounded audit read every line 3596-7811 of output/tau_f1_transcript_audit_2026-09-13/sources/audit_segment_U0041_U0054.md, in order, including every retained user and assistant message. Segment SHA256: e79b46722d9a2ee95b68ae6512f37a19fd41e4b3ecc4e53583cd357d0442c251. Locators below are one-based lines in that file, not lines in an inferred ZIP. The complete output/split_zero_rh_tandem_2026-09-12/sources/Tau_Base_Cohomology_2026-09-12/NOTE.md was also read. Its verified SHA256 is d03e71ad18f187bd89880cb8ca6fc9c5d6f260b3de8e8e5702c27db97e7b63c3.

Supplementary checking read the sum-connection NOTE.tex at output/split_zero_rh_tandem_2026-09-12/sources/web_sum_connection_delivery/Tau_Sum_Connection_Control/NOTE.tex, lines 176-287, 391-421 and 659-694. This is a bounded proof-window check of the Fisher identity, original relation derivative and explicitly stated transfer gap; it is not a claim to have audited that entire package or executed its regression suite. Earlier retraction, inverse-range and packet-section results cited by these episodes remain dependency inputs for the parent audit.

The original object is the four-point chart with $+$, $-$ $\leq \eta < \sigma$, the functor

$$A_\tau(F) = [F_+ \oplus F_- \xrightarrow{r_+ - r_-} F_\eta]$$

in degrees zero and one, its separately computed restriction to σ , and

$$K_\tau(W) = [I_\eta(W) \longrightarrow I_+(W) \oplus I_-(W)] \simeq S_\eta W[1].$$

Tau Base (21)-(25), (27)-(31), (38)-(48) retain the two-leg complex, supported copies of $\mathbb{Q}$, the adjoint, residue jets and tensor products. No message in the audited six episodes replaces this push-forward with the generic stalk or proves failure of the entire original programme. Later concentration on the one-leg complex has an exact relation to the joint complex, calculated below.

234.2 Episode ledger

234.2.1 LC49: U0049 $\rightarrow$ A1721, source boundary and control machinery

- User, line 3596, node a9162d93-9cf1-4d45-b6f1-9fd92ae43471, chain 3577: “then let us make the machinery for the deligne like control”.
- Progress A1696, line 3600, node 63828eab-7482-48e8-93d0-4fc0f615a74e, chain 3580.
- Final A1721, line 3604, node 40ab7ee4-4dcd-409c-9e0d-f211bc6aeccec, chain 3634; response ends at line 4262.

The requested calculation is source-side Deligne-like norm, duality and tensor control on the original arithmetic classes. The response expands the cutoff/moment commutator of the inherited continuous retraction, constructs finite representatives $R=s_Z\text{-}\Theta_{\text{tab}}$ with exactly unchanged $qR=\sigma_Z$ and $J_ZR=1$, and computes

$$B = DR - RA = \Theta K, \quad G = R^*R > 0, \quad W = A^*G + GA - G = -(R^*B + B^*R).$$

At line 3905 it explicitly says: “The boundary expression $[x\overline{F}H]_0^\infty$ vanishes by their stated decay.” This is an analytic endpoint boundary justified by the original test space, not a claim that the cohomological relation B has zero Hilbert pairing. Indeed the following subsection explicitly retains $\langle Rv, Bv \rangle$ and the difference of the two theta primitives in H^0 .

The residue calculation $A^*S+SA=S$ gives the exact metric transfer

$$G^D = S^*G^{-1}S, \quad W^D = -S^*G^{-1}WG^{-1}S.$$

This proves upper-to-lower transport, retaining the original weight-one action. It does not itself supply an upper arithmetic estimate. The tensor computation retains W_n as the sum of all n factor contributions, hence a copied error costs `nepsilon`. Its orbit-Gram construction has an exact endpoint identity; the endpoint has not been shown to be small on the actual arithmetic family.

The fixed cutoff example $r=s_0=1/4$, the nilpotent block and the off-line diagonal block are explicitly auxiliary calibrations. Their role is stated; the text does not identify them with actual zero packets or change $g=2xi$ to those examples. The malformed opening display $A^*GA+(\text{notused})$ is a presentation defect, immediately replaced by the correct infinitesimal identity, not a substantive mathematical obstruction.

Actual stopping point. Line 4259: “The uniform sublinear error estimate for the **actual arithmetic tensor family** is not proved here.” The answer builds the machinery the user requested; it does not finish the subsequent bound. The matrix certificate interface certifies supplied matrices with supplied error enclosures; no arithmetic integral or uniform family has been enclosed by that interface here.

Later completion. A1771 fixes the actual theta derivative filtration and derives its rank-two defect. A1829 supplies canonical full-jet interpolation, same-metric reflection and joint tensor corrections. Thus the later work does not merely leave the machinery at the orbit-metric stage.

Concrete continuation. Use the canonical representatives from A1829, calculate their arithmetic full-jet moment matrices and signed boundary forms with the inverse interpolation matrix retained, then estimate their relative extremum as k, M vary. Do not infer the missing smallness from $qB=0$, the fixed-cutoff inverse bound, or a calibration certificate.

234.2.2 LC50: U0050 → A1771, homotopy freedom and the original theta recurrence

- User, line 4263, node 95ddc7db-1037-4e47-b839-13eaece6695, chain 3635: “The other session is working on this. It may not have everything that it needs, but it’s still trying to work. Consider corrections if they are required and continue.”
- Progress A1722, line 4267, node ce1a8f2e-af6c-4022-8160-af9a12024a25, chain 3637; A1735, line 4271, node 3e321a1f-89f3-42a8-86a4-d6e948dde8b2, chain 3656.
- Final A1771, line 4275, node 552c8e45-2599-46da-8b95-214fa4d5ce0c, chain 3721; response ends at line 4891.

The response checks both homotopy equations and gives the entire continuous family

$$H_\alpha(b) = (\kappa b + \alpha(qb), \mathcal{F}^{-1}\alpha(qb)), \quad \alpha \in \text{Hom}_{\text{cont}}(Q, V).$$

It lifts the family through support synchronization and retains $\text{Hom}(H^1, H^0)$; line 4430 states: “synchronization supplies the common target; it does not remove the H^0 -class.” The zero composite $L \rightarrow \gamma L \rightarrow d\gamma L = 0$ establishes exactly why changing this homotopy cannot change the source boundary or control matrix. It then continues through the effective operation $R_T = R + \text{Theta} T$, with $K_T = K + D_V T - T A$.

The calculation fixes the actual theta seed $\phi_* = (4\pi^2 x^4 - 6\pi x^2) e^{-\pi x^2}$, $f_j = D^j \text{Theta} \phi_*$, $L_n = \text{span}(f_0, \dots, f_n)$, and the orthogonal representative $R_n = (1 - P_n) s_Z$. Every unscaled orthogonal norm $\text{mathfrak{h}}_n = \|u_n\|^2$ remains. Integration by parts gives the three-term recurrence, including the negative coefficient $-\text{mathfrak{h}}_n / \text{mathfrak{h}}_{n-1}$, and then

$$W_n = \mathfrak{h}_{n+1}(r_{n+1}^* r_n + r_n^* r_{n+1}), \quad G_n - G_{n+1} = \mathfrak{h}_{n+1} r_{n+1}^* r_{n+1}.$$

The derivative is typed $Q_{\{V_n\}} \rightarrow Q_{\{V_{n+1}\}}$. Its nonzero class at the old relation level is explicitly $-[u_{n+1}] r_n$, and the next transport makes it that receiving fibre’s supported zero. The response proves the relation-layer isomorphism rather than dismissing this as zero after quotient.

The least relative excess is reduced to an explicit two-by-two spectral calculation using $r_n G_n^{-1} r_n^*$, $r_{n+1} G_{n+1}^{-1} r_{n+1}^*$ and the mixed coefficient. Line 4821 stresses that “the inverse G_n^{-1} remains”. This is an exact finite reduction, not the evaluation or asymptotic control of those three quantities for arbitrary actual packets.

Numerical and boundary scope. The actual first four seed norms are evaluated; a double theta sum is integrated only after moving $(0, 1)$ to $(1, \infty)$ by the original inversion. The displayed integer-tail estimate is explicitly distinguished at line 4882 from validated rounding and inverse-matrix errors. It is not a certificate for a nonempty packet’s relative excess.

Actual stopping point. Line 4890: “A uniform small arithmetic excess has not yet been proved.” This is successful continuation through homotopy classification and an exact source recurrence, followed by a still-open quantitative calculation. The obstruction only says homotopy changes cannot change B ; it does not say original theta-boundary changes, or the programme, fail.

Later completion and next derivation. A1829 supplies the full-jet inverse-moment metric and its convergent tail, making the earlier inverse-conditioning issue explicit. The next work is the arithmetic asymptotic or certified finite evaluation of that retained two-row expression, not a new homotopy parameter search.

234.2.3 LC51: U0051 $\rightarrow$ A1829, canonical full-jet moment problem and joint tensors

- User, line 4892, node e8523a76-cc80-41ad-a0f0-f5ed9ad6ff3b, chain 3722: “The other session is continuing to try and formalize. This can happen, of course, while you also continue to work on pushing this through the program further. So continue doing that as you are.”
- Progress A1773, line 4896, node 11e00aa0-8036-4382-a795-16e531c812af, chain 3725; A1779, line 4900, node 560d9cac-da7f-4022-9dcc-22095069129f, chain 3732.
- Final A1829, line 4904, node aff5580e-a451-48c3-85f4-f19487a5d35e, chain 3826; response ends at line 5583.

The response acknowledges the previous metric-freedom calculation, then fixes the original L_n instead of optimizing unrestricted metrics. Its exact source remains $T_h(P) = P(D) F_h$, $MF_h = g/h$, with $T_h(hP) = \text{Theta}(P(D) \phi_*)$ and the arithmetic jet unit $\text{upsilon}_h = j_h(g/h)$. The polynomial family is therefore an explicitly mapped presentation of the original quotient, not a replacement family. The full-jet kernel is precisely hP_n in the one-factor source, and the original

relation ideal in the tensor source.

It proves the constrained minimum formula

$$d\nu_h(t) = \left| \frac{g(1/2 + it)}{h(1/2 + it)} \right|^2 \frac{dt}{2\pi}, \quad G_{h,n} = (J_{h,n+d} M_{h,n+d}^{-1} J_{h,n+d}^*)^{-1}.$$

The packet inclusions retain their arithmetic units and every nilpotent jet; the exact multiplication $P \rightarrow (H/h)P$ is an isometry between the two specified measures. The reflection acts on the same canonical metric and pairs the generalized control eigenvalues with their negatives. This completes a compatibility issue left by transferring an upper bound to a different dual metric in A1721; it still supplies no small upper bound.

The density calculation proves the original $D^{\wedge n} \mathbf{f}_0$ family dense in $L^2(dx)$, hence $G_{\{h, n\}} \rightarrow 0$, but simultaneously proves every nonzero dual row diverges against $G_{\{h, n\}}^{-1}$. The exact Hilbert quotient map is $Q \rightarrow H/\text{closure}(\Theta \tau V) = 0$; this map is explicitly distinguished from the original Frechet quotient Q . Its supported lift sends a class to $\mathbf{e}$, not to τ . This is an exact obstruction to reading arithmetic purity off absolute Hilbert decay, with the original class and its jet still present. It is not failure of A_τ or K_τ .

The joint total-degree source and ideal are explicitly constructed. The next relation layer has dimension $\text{binom}(M+k, k-1)$, and the actual maps $Y_{\{k, M\}}, C_{\{k, M\}}$ give

$$W_{k,M} = -(Y_{k,M}^* C_{k,M} + C_{k,M}^* Y_{k,M}), \quad G_{k,M} - G_{k,M+1} = Y_{k,M}^* Y_{k,M}.$$

All tensor primitive signs are retained. This is a real change to admitted original boundaries, not the unsupported inference that a smaller Gram matrix has smaller relative defect.

Actual stopping point. Line 5580: “No uniform sublinear excess has been established in this continuation.” The eigenline diagnostic remains exactly $k(2\text{Re}\rho - 1)$ independently of the chosen positive metric. The source equations and moment problem are completed; the arithmetic extremal estimate is not.

Later completion and next derivation. A1859 gives finite highest-layer coordinates, a proved finite bound and a signed symmetry restriction. The surviving task is bounding the actual recurrence coefficients and full-jet interpolation increments together; independent positivity of the measure, shrinking Gram matrices, or the bare existence of the moment inverse are insufficient.

234.2.4 LC52: U0052 $\rightarrow$ A1859, finite bound and signed symmetric summand

- User, line 5584, node af10d798-2756-445d-9e9b-5c7b064cade9, chain 3827: “Yeah, let’s push that.”
- Progress A1831, line 5588, node fe850773-525d-45f2-a728-1fbb3b854c75, chain 3830.
- Final A1859, line 5592, node f39f3d53-73e5-40f4-bdf0-25c37492dba8, chain 3887; response ends at line 6332.

The response constructs and inverts the map $\mathbf{b}_M = \mathbf{T}_+ - \mathbf{R}_M \mathbf{F}$ from the next homogeneous polynomial space to the actual next theta-relation layer. It computes the exact Gram $\Omega_{\mathbf{G}_M} + \mathbf{F}^* \mathbf{G}_M$, retains every raw norm and actual measure mass, and proves the Woodbury metric update. The inverse metric obeys

$$\mathcal{C}_{M+1} = \mathcal{C}_M + \mathbf{F} \Omega^{-1} \mathbf{F}^*, \quad \mathcal{Z}_M = \mathbf{A}_k \mathcal{C}_M + \mathcal{C}_M \mathbf{A}_k^* - k \mathcal{C}_M = \mathbf{F} \Omega^{-1} \mathbf{E}_+^* + \mathbf{E}_+ \Omega^{-1} \mathbf{F}^*.$$

The recurrence retains $\text{Reb}_n = 1/2$ and potentially nonzero Imb_n ; it does not silently impose an even measure for an arbitrary reflection-stable packet. It proves the finite upper and lower estimate $\epsilon_{\{k, M\}} \leq 2\sqrt{\Gamma_{\{k, M\}} \lambda_{\{k, M\}}}$. Line 6013 explicitly limits

this: “Its constants have not yet been bounded sublinearly in tensor degree.” The sharper signed finite matrix is retained after Cauchy–Schwarz, so discarded phases are not silently identified with the original form.

The signed cochain idempotent $(1/k!) \sum \text{sign}(\pi) T_\pi$ cancels the Koszul sign in top degree and selects ordinary symmetric tensors. It keeps every repeated eigenvector $v^{\{\text{tensork}\}}$, unscaled orbit sums, all factorial orbit masses, and the complement with its exact trace. The smaller module is a computed direct summand, not a deletion of off-line spectral witnesses.

The Gaussian repeated-root comparison is explicitly a calibration. The arithmetic measure remains $|2xi/h|^2 dt/(2\pi)$ throughout the proposed application; the literal Gaussian mass $\sqrt{2\pi}$ is retained in the test. The response also reports a smaller-degree example where enlarging the correction space increases the relative excess. This is a legitimate counterexample to a naive monotonicity claim, not to all possible arithmetic asymptotics.

Actual stopping point. Line 6327 again states that uniform sublinear excess for the actual arithmetic family “has not been proved here.” The finite bound meets part of the requested push; its constants and signed cancellation have not been estimated in the required limit.

Later completion and next derivation. A1912 transforms this same matrix problem to a sum-coordinate matrix weight, preserving the relative fibres. One must estimate the actual signed frontier matrix or the combined arithmetic Γ_λ cost after that exact transformation. The Gaussian improvement cannot supply that estimate.

234.2.5 LC53: U0053 → A1912, exact sum descent but no improvement of the constant

- User, line 6333, node bbd82b42 - aa50 - 4eeb - abf3 - 27b7320953d3, chain 3888: “Okay, yeah, continue.”
- Progress A1860, line 6337, node 275efe72 - c7eb - 4763 - 82d1 - 9bf3ce0e3186, chain 3890.
- Final A1912, line 6341, node 64c5b883 - 17ba - 441a - b5c9 - bfa6ff1ef787, chain 3986; response ends at line 7043.

The response performs an exact change of presentation using $S = \sum s_i$, not a replacement of g . In the symmetric square it keeps $\Delta = (s_1 - s_2)^2$, proves the invariant quotient $(H_0, \Delta H_1)$ including collisions, and supplies its original theta primitives with both tensor signs. The real change of variables retains Jacobian $1/2$ and the relation $\Delta = -v^2$ in every matrix-weight entry.

The scalar convolution is only the $(0, 0)$ entry. Every relative-coordinate moment remains in the full positive matrix $\text{mathsf{W}}(u)$. The triangular square-completion map is invertible, but its coefficient $m_{0^{\{-1\}}b}$ need not be polynomial. The response explicitly keeps the exact image of the original filtered polynomials instead of enlarging to arbitrary sections. This avoids an otherwise serious source substitution.

The coordinate congruences $M' = T^*MT$, $J' = U^{\{-1\}}JT$, $G' = U^*GU$, $W' = U^*WU$, $R' = RU$ prove that the generalized control constants are unchanged. Line 6788 says precisely: “The new operation has not manufactured a smaller constant.” This is an explicit preservation theorem, not the bound requested by the wider programme.

The finite sum-line module dual is computed by the SI - A resolution, retaining the full resolvent and every nilpotent ladder. Its scalar trace is a further observation. The displayed $\text{RHom}_{\{C[S]\}}(B_k, -)$ belongs to a restriction-of-scalars category; it is not identified in this episode with the original chart functor K_τ . Tau Base already supplies a finite-jet morphism to the K_τ dual. Reattaching the new dual through that original finite-jet morphism is the concrete task, rather than calling the two right adjoints identical or unrelated.

Actual stopping point. Line 7038: “A uniform sublinear tensor excess has not yet been estab-

lished.” The response leaves explicit arithmetic convolution mass, relative covariance and full-jet interpolation as the unestimated quantities. The finite pushforward’s lack of an identified Deligne Lefschetz-pencil realization is stated with exact scope; no general failure theorem follows.

Later completion and next derivation. A1959 differentiates the actual sum amplitude, proves a mass-retaining scalar contraction, computes the full matrix connection and normal part, and adds the missing frame derivative $C^{\{-1\}}C'$. Those are genuine later completions of part of the analytic work. The still-missing estimate is on the original degree-constrained relative image, not on the unrestricted direct-sum space produced by pointwise square completion.

234.2.6 LC54: U0054 → A1959, real Fisher estimate; missing transfer to the arithmetic extremal form

- User, line 7044, node 9cde09a7-2e48-4d0c-aa8b-4d54a316f9b9, chain 3987: “ok the formalizing is in progress - you work on this”.
- Progress A1914, line 7048, node c84c5062-8d5b-45fb-8eea-c0f4c924908e, chain 3990; A1936, line 7052, node 951e58ad-9a13-43d3-847c-6b57a8616eef, chain 4024.
- Final A1959, line 7056, node ac351c92-ca3e-47a6-9014-85f239a2760e, chain 4075; response ends with the segment at line 7811.

The source amplitude is the actual $a_h(t) = (g/h) (1/2 + it) / \sqrt{2\pi i}$, with unchanged mass $\mu_h = |F_h|^2$. Reflection gives fixed real or imaginary phase, justifying the exact Fisher identity without requiring a bounded logarithmic derivative at zeros. In centered sum coordinates the Jacobian is one. The response proves

$$\mathcal{I}_{h,k} + 4 \int \|n_k(u)\|^2 du = \frac{\mu_h^{k-1}}{k} \mathcal{I}_h.$$

The proof retains all diagonal terms, computes all distinct-index cross terms as $\mu_h^{k-2} |\text{intconjugate}(a_h) a_h'|^2 = 0$, and retains the normal residual by orthogonal decomposition. The endpoint zero is justified by Schwartz decay after the exact Mellin–Fourier transform. The mass is never set to one. This is a completed analytic calculation on the actual arithmetic seed family.

Line 7333 states: “The scalar calculation is only the constant relative column.” The full relative family then has exact matrices $\text{mathsf{fW}} = j^* j$, $\text{mathsf{fB}} = j^* j'$, $\text{mathsf{fT}} = (j')^* j'$, connection $\text{Gamma} = \text{mathsf{fW}}^{\{-1\}} \text{mathsf{fB}}$, normal map $N = (1 - \text{Pi}) j'$, and full energy

$$\|\partial_u(j_u c)\|^2 = (c' + \Gamma c)^* \text{W} (c' + \Gamma c) + c^* N^* N c.$$

The connection formula correctly retains the extra $C^{\{-1\}}C'$ under a changing frame and the potentially noncommuting product $\text{mathsf{fW}}' \text{mathsf{fW}}^{\{-1\}} \text{mathsf{fW}}'$. Neither matrix term is bounded on the whole degree-constrained source in this response.

The exact observable dictionary is

$$\mathcal{U}_k D^{(k)} = (k/2 + iu) \mathcal{U}_k, \quad \partial_u \mathcal{U}_k = i \mathcal{U}_k \mathcal{L}_k, \quad \mathcal{L}_k = \frac{1}{k} \sum \log x_i, \quad [D^{(k)}, \mathcal{L}_k] = -1.$$

Thus the new differential estimate concerns a conjugate observable, not the original generator defect W_M . The response does not conflate them; it exhibits their exact commutator and filtered graph. It also calculates the response of actual theta relations: $J_h(\log x \text{Thetaphi}) = j_h(g') j_h(H_{\text{phi}})$, the complete conormal thickening P/I^2 , its derivative map, the local arithmetic unit correction, and higher relation layers. These carry the original multiplicities and lead to the same residue trace contraction as Tau Base (44)–(45).

Actual stopping point. Line 7790: “It is not yet a uniform sublinear bound for every relative polynomial direction in W_M .” This statement has exact mathematical content. Neither the full-matrix energy identity nor the conormal map supplies a quantitative comparison between all admissible coefficient functions and the inverse full-jet interpolation metric. The only displayed numerical arithmetic evaluation is for $h=1$; line 7807 expressly says it is not “a substitute for a nonempty arithmetic packet.”

Later completion. None occurs inside this audited segment. The supplementary source windows confirm that the final note itself states the same transfer gap. Any later completion must be matched to its actual subsequent turns; it cannot be inferred from a later ZIP title.

Concrete continuation. Retain the exact least-norm coefficient lift $C_{\{k, M\}} = M_{\{k, M\}}^{\{-1\}} J_{\{k, M\}}^* G_{\{k, M\}}$. Substitute its actual coefficients into both terms of the full derivative energy, retaining the normal matrix and the frame derivative. Evaluate the corresponding finite quadratic forms and the original signed $W_{\{k, M\}}$ in the same quotient coordinates; control the change between them using the original theta boundary equation. Track $\mu_h^{\{k-1\}}$, all packet-unit jets, the polynomial degree, tensor degree and inverse interpolation matrix. An estimate of $I_{\{h, k\}}$ alone, or a proof that the two differential pieces are retained, does not complete this calculation.

234.3 Two completed source-comparison calculations for the audit

234.3.1 A. The one-leg complex is an explicit equivariant retract of the original joint push-forward

Let F denote the original even Fourier involution on V , so $F^2=1$. In the original coordinates put

$$C_{\tau} = [V \oplus V \xrightarrow{\Theta(\phi - \mathcal{F}\psi)} \mathcal{B}], \quad C_{+} = [V \xrightarrow{\Theta} \mathcal{B}].$$

Define degree-zero and degree-one maps

$$i^0(v) = (v, 0), \quad i^1(F) = F; \quad p^0(\phi, \psi) = \phi - \mathcal{F}\psi, \quad p^1(F) = F.$$

The equations $d_{\tau} i^0 = i^1 \Theta$ and $\Theta p^0 = p^1 d_{\tau}$ follow directly from the displayed original differential; therefore these are chain maps, and $p i = 1$. Their complementary map in degree zero is

$$(1 - ip)^0(\phi, \psi) = (\mathcal{F}\psi, \psi),$$

and in degree one is zero. Its image is the full original kernel, not a vanished subspace. Explicit mutually inverse chain maps are

$$C_{\tau} \longrightarrow C_{+} \oplus V[0], \quad (\phi, \psi) \longmapsto (\phi - \mathcal{F}\psi, \psi),$$

$$C_{+} \oplus V[0] \longrightarrow C_{\tau}, \quad (v, w) \longmapsto (v + \mathcal{F}w, w),$$

with the identity on the degree-one copy of $\mathbf{mathscr{B}}$. Every component is continuous in the original Schwartz topology. Under τ Base (34), the joint action is $(U_{\phi}, aU_{\{1/a\}\psi})$. Since $\mathcal{F}(aU_{\{1/a\}\psi}) = U_{\mathcal{F}\psi}$, the first factor has exactly U_a , and the retained second factor has exactly $aU_{\{1/a\}}$. Thus this is an equivariant chain splitting with the full action, not a replacement by identical actions on both legs.

In the split reconstruction, the actual map from the single + support fibre to the joint fibre inserts the supported zero in the minus leg. It is the existing support transport and preserves the nonempty

mask. External absence maps to external absence. No assertion that this linear direct-sum description erases other support fibres is made.

Consequently every one-leg $H^1=Q$ calculation has the identity comparison to the original $H^1 A_{\tau}(T)=Q$, while the original $H^0=V$ remains in the explicit complementary complex. Applying the original adjunction to this actual split complex gives

$$R\mathrm{Hom}_E(C_{\tau}, W) \cong R\mathrm{Hom}_E(C_{+}, W) \oplus \mathrm{Hom}_E(V, W)[0].$$

In degree minus one the comparison is precisely $\mathrm{Hom}(Q, W)$, hence the finite-jet dual maps in these episodes land in the same original $H^{-1} R\mathrm{Hom}_A(T, K_{\tau}(W))$ from Tau Base (28),(43). This proves the relevant source and adjoint comparison rather than calling the two presentations unrelated.

234.3.2 B. The announced global logarithmic-relation map and its exact full-jet image

Use the original $LF(x)=(\log x)F(x)$ on $\mathrm{mathscr{B}}$. This is a continuous endomorphism: differentiating LF finitely many times produces the original derivatives of F times $\log x$ or constants; for every integer weight b , $|\log x| x^b$ is bounded by a constant times $x^{b-1}+x^{b+1}$. The seminorms in Tau Base (11) therefore control all resulting terms. Define

$$\nu : V \longrightarrow Q, \quad \nu(\phi) = q(L\Theta\phi).$$

This is a continuous linear map using the original quotient topology. In original unshifted coordinates,

$$U_a L = (L - \log a)U_a, \quad U_a \Theta = \Theta U_a, \quad q\Theta = 0.$$

For each ϕ_i their direct substitution gives

$$U_a \nu(\phi) = qU_a L\Theta\phi = qL\Theta U_a\phi - (\log a)q\Theta U_a\phi = \nu(U_a\phi).$$

Similarly $DL=LD-1$ and $D\Theta=\Theta D_V$ imply $D_Q\nu=\nu D_V$. Thus A1936's announced global map has a complete equivariance proof without discarding the commutator; the commutator term is an actual original theta relation before its quotient.

For a finite packet $h=\mathrm{prod}(s-\rho)^{\{m_{\rho}\}}$ with complete actual orders, the original Mellin identity gives

$$J_h \nu(\phi) = j_h(g') j_h(H_{\phi}).$$

For every polynomial P , the actual source $\phi=P(D_V)\phi^*$ lies in V , since differentiation preserves both zero moments, and $H_{\phi}=P$. Polynomial reduction is onto E_h ; hence the exact image, not just an inclusion, is

$$\boxed{J_h \nu(V) = j_h(g') E_h.}$$

At a selected root write the original germ as $g=u_{\rho}(z)z^{\{m_{\rho}\}}$, with the original nonzero unit u_{ρ} . Differentiation gives

$$g' = m_{\rho} u_{\rho}(z) z^{m_{\rho}-1} + u'_{\rho}(z) z^{m_{\rho}} \equiv m_{\rho} u_{\rho}(0) z^{m_{\rho}-1} \pmod{z^{m_{\rho}}}.$$

Therefore multiplication by g' has image the full one-dimensional socle $Cz^{\{m_{\rho}-1\}}$ in each local factor. Its kernel is (z) in that factor, including the case $m_{\rho}=1$, when $(z)=0$ and the image

is the whole factor. On the complete packet its rank is exactly the number of distinct selected roots and its kernel dimension is $\text{sum_rho}(m_rho - 1)$. No nilpotent jet has been declared absent: the derivative reads its socle through a fully specified contraction.

Finally Tau Base (42) gives, for this exact image,

$$R_Z(f, J_h \nu(P(D_V)\phi_*)) = \sum_{\rho \in Z} \text{Res}_\rho f^\dagger P \frac{g'}{g} ds = \sum_{\rho \in Z} m_\rho \overline{f(1 - \bar{\rho})} P(\rho).$$

The second equality follows from $g' / g = m_rho / z + u_rho' / u_rho$; the unit term is holomorphic and has zero residue. This completes the global equivariance and the exact arithmetic image behind the final episode's trace formula. It does not establish a positivity or tensor-growth bound.

234.4 Integration judgment and priority

These six episodes contain substantial mathematical continuation, including analytic work on the original theta source. Their repeated endpoint is an uncompleted arithmetic uniform estimate. A passage-by-passage audit should identify that endpoint without relabelling legitimate computations or precisely scoped obstructions as abandonment of all mathematics.

The main redo request should resume the final filtered matrix-weight comparison, with A_tau , K_tau , the actual $g=2 \times i$, the arithmetic unit, all local jets, supported relation layers and original actions attached. The following shortcuts are specifically excluded by the calculations already present: treating a theta boundary as an orthogonal vector; choosing an arbitrary favourable metric; reading purity from $G_n - > 0$; promoting an auxiliary Gaussian example; dropping the complement of the signed symmetric projector; replacing the full relative matrix by its scalar convolution entry; assigning unit mass; or replacing the conjugate logarithmic observable by $D^\wedge(k)$.

The tractable comparison calculations above can be integrated immediately. The harder continuation is the explicit all-direction arithmetic interpolation estimate left at A1959, not a new generic RH equivalence or an unspecified purity assumption.

235 Late analytic control: U0055–U0067

236 Late mathematical continuation audit: U0055–U0067

The late segment contains substantial completed mathematics and an unresolved arithmetic estimate. It does not support a blanket finding of abandoned work or a collapse of the original global τ -base cohomology to the Boolean stalk. The exact counterexamples in the final response refute a particular auxiliary-purity inference. They do not refute the complete original construction.

236.1 Reading and evidence scope

All supplied segment text and both required primary notes were read completely. Quotes below are exact substring-validated against current segment. Claims about earlier deliverables are credited at their supplied written-proof scope, not presented as a fresh independent audit of every predecessor source. Parent separately owns gamma/purity replay and integration.

The source UUID and ordered U/A locator are primary. The source owner corrected only newline serialization after the full read; hashes below pin the current serialization. Every quoted passage is checked as an exact substring against it. No remote/master/Lean work was performed in this lane.

Public locators identify the cited sources; the byte counts and hashes below remain those of the original source witnesses. The first locator is a source record, not the private conversation.

236.2 Original controlling objects

The complete primary Tau Base note defines the structural blueprint map to $\mathfrak{b}_\tau$, the four-point chart $+, - < \eta < \sigma, \mathcal{A}_\tau(F) = [F_+ \oplus F_- \rightarrow F_\eta]$, its separate derived restriction to $F_\sigma, K_\tau(W) \simeq S_\eta W[1]$, supported $H^1 = Q$, the full Mellin-jet/right-adjoint injection, and $H^k \mathcal{A}_{\tau,k}(\mathcal{T}^{\boxtimes k}) = Q^{\otimes k}$. None is replaced by the Boolean generic stalk in this audit. The primary note itself proves the comparison and preserves both roles.

U0065 has an empty visible text body. Its existence and the answer's references to a new attachment are recorded without inventing a user request. U0063 has two substantive assistant deliveries before the next user turn; both are included.

236.4 L01. Cyclic sum source: genuine comparison, unfinished growing-degree estimate

Episode: U0055 (2d52f35c - ff35 - 4c03 - 8b7b - e12936f56b7f) → A1998 (f352dc2c - 6b62 - 4095 - a3f1 - a4ecc7422ec9, chain 4156, current segment line 13).

User input, verbatim:

Okay, then we continue with this. - you push math other formalizes github updates are in progress it remains for you yto push this through the program

Classification: substantive continuation; quantitative target explicitly open.**Exact passages:**

- A1960 (278d589e - 2a87 - 4b7e - b8fe - 3dd05bfceba7, chain 4078): “carrying the $1/k$ estimate through relative polynomial directions and the actual arithmetic quotient.”
- A1998 (f352dc2c - 6b62 - 4095 - a3f1 - a4ecc7422ec9, chain 4156): “A uniform sublinear bound for that calculated constant is **not established in this continuation.**”

Original objects and maps. Original $C_+ = [V \rightarrow \Theta B]$, $Q = B/\Theta V$, $g = 2\xi$; $B_k = E_h^{\wedge k}$, $S = \Sigma s_i$, $U_k = v_h^{\wedge k}$; $\alpha: C_{\{h,k\}} \rightarrow B_k^{\wedge \{S_k\}}$, $\eta = M_U \alpha$, $\pi\eta = 1$; original relation ideal I_k and all $I_k^{\wedge r}$.

What is calculated. The answer constructs the cyclic injection and an equivariant retraction, calculates its complementary trace, retains maximal nilpotent lengths at coinciding sums, proves the source norm is $w_h^{\wedge \{k\}}$, derives $\text{rank} \leq 2$ control, and calculates all polynomial derivative moments. The cross contribution $(k-1)z^2 M(z)^{\wedge k}/(4k)$ is retained; it vanishes only for the zeroth moment. It also computes $I_k^{\wedge r} \cap C[S]$ and the derivative of the full Taylor unit.

What is not finished. The constant-column Fisher factor $1/k$ has not been converted into an upper bound for $\varepsilon_{\{h,k,N\}}$ when $N \geq \deg \chi_{\{h,k\}} - 1$ grows with k . The inverse interpolation Gram and all weighted derivative moments still enter.

Exact scope. No obstruction to A_{τ} or K_{τ} is proved. The cyclic source is connected by injection, retraction, complementary trace, and a nonorthogonal metric correction, so this is not an unsupported replacement of the full tensor module.

Later completion or repair. A2058 strengthens the lower target through exterior powers. A2101 computes the exact volume formula. A2177 later proves a required norm-window estimate; none proves the original sublinear upper estimate.

Concrete continuation. Reuse η and π with their actual metric correction, then calculate the source-specific determinant or control quantity at admitted $N(k)$. Do not reuse the zeroth-moment $1/k$ estimate as a uniform polynomial estimate. The shifted-Mellin appendix now computes additional weighted-source inputs, with inverse costs retained.

236.5 L02. Exterior amplification is completed; it does not constitute the upper estimate

Episode: U0056 (57281c24-0419-4dc1-b121-02b753cbdf9f) → A2058 (9780ca43-7a87-4522-b34f-347751ad3149, chain 4273, current segment line 882).

User input, verbatim:

Yeah, then the next thing is just do, continue program. If GitHub has any genuine corrections, it is worth those should obviously be integrated.

Classification: completed amplification and corrections; upper estimate open.

Exact passages:

- A2058 (9780ca43-7a87-4522-b34f-347751ad3149, chain 4273): “The new lower bound and the exterior comparison are proved below. The subcubic arithmetic upper estimate is not yet proved.”
- A2058 (9780ca43-7a87-4522-b34f-347751ad3149, chain 4273): “The polynomial-degree cost remains.”

Original objects and maps. $C=C_{\{h,k\}}$, original G_N , $H_N=G_N^{-1}W_N$, full generalized $E_{>}$, ordinary exterior powers, $p!$ source Gram, degree- k Koszul permutations, full theta primitive.

What is calculated. The rank-two trace-zero control has eigenvalues $\pm \varepsilon_N$. Its additive exterior action has the same allowance, not p times that allowance. The determinant line of $E_{>}$ yields $L_{\{h,k\}} \leq \varepsilon_N$. The exact quartet count is $q_k = [1 + k(m-1)](k+1)^2$ and $L_{h,k} = 2\delta[1 + k(m-1)](k+1) \text{ floor}((k+1)^2/4)$. The empty-packet and oblique-projector corrections are explicitly integrated.

What is not finished. No admitted $N(k)$ is shown to have $\varepsilon_N = o(k^3)$. In particular the degree requirement $N \geq q_k - 1$ prevents treating the preceding polynomial estimates as fixed-degree estimates.

Exact scope. This is a valid strengthened lower obstruction under the original hypothetical off-line quartet, not an argument that such a quartet exists or that the program fails.

Later completion or repair. A2101 and A2129 represent the same quantity through volumes and a Gamma comparison. A2177 proves the actual norm factor; A2266 later integrates threshold four.

Concrete continuation. Keep the full quartet multiplicity and both original endpoint windows. Apply source-specific analytic estimates to those windows rather than iterating an exterior operation at no cost.

236.6 L03. Toda determinants and phase are calculated; seed numerics do not certify packet asymptotics

Episode: U0057 (ab287a86-8dcf-4adb-acf3-2360429784f8) → A2101 (7e3bf622-950d-4b0b-8707-50208e2c8efb, chain 4347, current segment line 1552).

User input, verbatim:

Okay, argument's downloaded, fed to the GitHub as well. They are working on this, so continue as well.

Classification: completed finite identity and analytic moment representation; asymptotic bound open.

Exact passages:

- A2101 (7e3bf622-950d-4b0b-8707-50208e2c8efb, chain 4347): **"I have not proved that this quantity tends to zero."**
- A2101 (7e3bf622-950d-4b0b-8707-50208e2c8efb, chain 4347): "At $h = 1$, the finite arithmetic quotient is zero."

Original objects and maps. $M_h(\theta) = \int e^{\theta t} |(g/h)(1/2+it)|^2 dt / (2\pi)$; $Z = M_h^k$; relation filter $\bar{\chi}(c-i\partial\theta)\chi(c+i\partial\theta)$; source and relation Hankel determinants; $V_N = D_{\{N+1\}}/B_{\{N-q+1\}}$.

What is calculated. The Schur-complement determinant ratio, source and relation Toda flows, incoming/outgoing source maps, phase $z_N/\omega_N = i(\text{Tr } T - \partial\theta \log V_N)$, and exact control formula including phase and imbalance squares are calculated. A separate first-admissible-degree formula avoids a singular preceding inverse. Actual $h=1$ theta-seed numerical values are identified as noninterval, empty-packet tests.

What is not finished. The source-boundary determinant ratios are not bounded uniformly on $N \approx q_k$, and their numerical condition numbers are not controlled. The $h=1$ evaluations do not evaluate a nonempty actual zero packet.

Exact scope. A positive source Gram and positive relation Gram do not fix the sign of their curvature difference. This precise limitation does not negate their exact relation to the arithmetic quotient.

Later completion or repair. A2177 completes a missing norm-window subestimate. A2611 later shows a Gamma-only subthreshold volume inference fails, leaving the signed arithmetic correction.

Concrete continuation. Calculate the actual signed four-window log-volume contribution from g/h . Use the exact equality before discarding its two squares, and retain the source and relation determinants in the same arithmetic measure.

236.7 L04. Gamma descent preserves the source but its one-sided bound cannot control consecutive ratios

Episode: U0058 (5a0c5812-2163-49b2-81e1-eb86a33603b0) → A2129 (5bee5948-a4ef-43bd-b118-27b0d7bf29c7, chain 4397, current segment line 2260).

User input, verbatim:

It appears that the other session's work is just being straight updated on GitHub. So there is not really a particular reason for me to keep posting everything that it does here verbatim. You can just look in that vein, continue while it also continues, and you both just work via there. Codex is also working from that same GitHub, so it should just work out. continue workin

Classification: completed reference comparison; explicit one-sided gap.

Exact passages:

- A2129 (5bee5948 - a4ef - 43bd - b118 - 27b0d7bf29c7, chain 4397): “**The one-sided bound $T_N \leq C_h^{kq}$ does not bound that consecutive ratio.**”

Original objects and maps. Actual $w_h = B_{\{h,\lambda\}r_\lambda}$; scalar-sum inclusion U_Σ and adjoint C_Σ , relative residual; exact mass c_λ^k ; $m_{\{h,k\}} = r_{\{\lambda,k\}} B_{\{h,\lambda;k\}}$; G_N^{ar} and G_N^Γ linked through the same χ -relations.

What is calculated. Gamma convolution, all polynomial conditional projections and residual norms, actual bounded multiplier, finite 2N-moment closure, representative correction in the original relation space, one-sided $G_N^{\text{ar}} \leq C_h^k G_N^\Gamma$, and a finite moment-tail bound are established in the response.

What is not finished. Neither $T_{\{N-1\}}/T_{\{N+1\}}$ nor the signed four-window correction is bounded by the individual upper values $T_N \leq C_h^{kq}$. A compact-interval quadrature error and high-degree inversion error also remain unevaluated.

Exact scope. The Gamma source is an explicitly compared auxiliary norm, not the arithmetic object. No claim of source equality or purity follows from the bounded multiplier.

Later completion or repair. A2177 supplies a lower envelope after actual convolutions for a norm estimate. A2611 supplies the explicit Gamma obstruction and the exact arithmetic correction that remains.

Concrete continuation. Calculate $\log(T_{\{q-1\}}T_q/(T_{\{2q-1\}}T_{\{2q\}}))$ with its signs using the original multiplier. Root’s separate determinant-interpolation calculation is the current continuation; do not redo a generic Gamma theorem.

236.8 L05. The missing arithmetic norm-window estimate is actually proved

Episode: U0059 (f7016d71 - f91a - 4287 - a3f6 - 72408e4f8312) → A2177 (da706e04 - bfb8 - 4d3f - 9747 - 194c30e053b2, chain 4483, current segment line 2951).

User input, verbatim:

the formalization session has been working - including a check for delignes work again (which you have in workspace I think latex) - continue pushing through

Classification: completed requested analytic subestimate; weaker volume threshold later strengthened.

Exact passages:

- A2177 (da706e04 - bfb8 - 4d3f - 9747 - 194c30e053b2, chain 4483): “**One of the analytic estimates in the new endpoint criterion is now proved for the actual arithmetic measure.**”
- A2177 (da706e04 - bfb8 - 4d3f - 9747 - 194c30e053b2, chain 4483): “**Neither upper estimate is being claimed here.**”

Original objects and maps. Original w_h , local mass of ζ on $[T-1, T+1]$, triple-convolution lower envelope, monic polynomial quotient $P_n/P_{\{n-1\}}$, same arithmetic relation $\chi P_{\{n-q\}}$, endpoint window $q_k \leq N < 2q_k$.

What is calculated. The response gives a local zeta mass proof via an explicit ellipse and interpolation from $\text{Re } s=2$, carries it through g/h , constructs the triple-convolution lower envelope, and combines it with actual exponential moments and the exact Legendre monic norm to prove $(\omega_{\{h,k,2n\}}/\omega_{\{h,k,n\}})^{1/(2n)} \leq C_h n$ for $n \geq k \geq 3$. It then obtains the weaker combined $\liminf$ threshold 2.

What is not finished. The opposing four-volume upper bound remains open. The literal positive constants in the existence proof are not interval-certified numerical values, which the response expressly states.

Exact scope. This is evidence against describing all of the late work as abandoned calculation: it closes an arithmetic estimate previously left in a handoff. It does not itself prove the entire endpoint program.

Later completion or repair. A2266 explicitly integrates the stronger per-window propagation from the parallel session, making the combined lower threshold 4. The earlier threshold 2 is superseded, not a contradiction.

Concrete continuation. Preserve this arithmetic theorem and its comparable-window extension. Use threshold four in the final continuation; calculate the remaining source-relation volume correction, not another proof of the already completed norm factor.

236.9 L06. Finite restriction certificates do not control their growing source gaps

Episode: U0060 (a7c1ac63 - a259 - 43d4 - 92a9 - 3cfac7b244ec) → A2225 (3fe5603d - ea16 - 4fb3 - b0d0 - 995546d1c47a, chain 4571, current segment line 3535).

User input, verbatim:

alright nice work keep it up

Classification: completed exact comparison and finite upper interface; uniform input absent.

Exact passages:

- A2225 (3fe5603d - ea16 - 4fb3 - b0d0 - 995546d1c47a, chain 4571): “Finite existence of a positive gap does not establish that uniform bound.”

Original objects and maps. Canonical return map $T_{\{i,j\}} = K_i G_j$, original source projection, original boundary $d_{\{i,j\}} = L R_i - R_j$, loss $H = I - T$, Cauchy–Binet full-jet determinant expansion.

What is calculated. The metric adjoint, composition law, arithmetic-action commutator, exact boundary Gram $G_i - G_j$, restriction eigenvalue log-volume formula, full-jet exterior expansion, and convergent trace-series enclosure are derived. The certificate is improved on a declared mass-seven Gaussian fixture with nilpotents retained.

What is not finished. The positive lower gap g_0 and trace moments for the original growing quartet source are not given bounds. The finite certificate is therefore not yet an evaluated arithmetic upper estimate.

Exact scope. The explicit assumption $K_i \geq g_0 K_j$ is an input to a finite enclosure, not a theorem that the actual source has a uniform gap. It must not become a substitute for calculating that gap.

Later completion or repair. A2266 removes the need for a separately supplied gap by deriving a spectral cap from two actual cost traces, but those traces still require arithmetic control.

Concrete continuation. Use actual g_0 from the finite matrices, or the later two-trace bound; calculate the source-dependent inputs. Keep the commutator so cost eigenspaces are not silently made A-invariant.

236.10 L07. Two-trace determinant majorant completes a finite problem, not the arithmetic growth problem

Episode: U0061 (0c7be9fa - 170d - 4376 - a60c - 0289f518269e) → A2266 (6ddefeaa - 3ad8 - 4e41 - 887d - 63764606478c, chain 4647, current segment line 4185).

User input, verbatim:

on the matter the othjer ones work too so cotinue with thsk work

Classification: completed sharper finite certificate and threshold correction; arithmetic traces unbounded.

Exact passages:

- A2266 (6ddefeaa-3ad8-4e41-887d-63764606478c, chain 4647): “Their required uniform growth bounds along the quartet family are **not proved here**.”
- A2266 (6ddefeaa-3ad8-4e41-887d-63764606478c, chain 4647): “the combined four-volume threshold is **four**, rather than the earlier weaker threshold two.”

Original objects and maps. $Z_{\{i,j\}} = (K_j - K_i)G_i$ in original G_i ; $t_1 = \sum b_n G_i b_n / \omega_n$, $t_2 = \sum / b_n G_i b_m|^2 / (\omega_n \omega_m)$, $A_2 = (t_1^2 - t_2) / 2$; exact θ -relation block.

What is calculated. The sharp determinant majorant from q, t_1, t_2 is proved by an explicit positive integral remainder. The bound retains cross-pairing areas, constructs a spectral cap, gives a third-trace subtraction, and composes with the actual consecutive-window theorem including the first degree.

What is not finished. The two actual arithmetic cost traces at degrees up to $2q$, requiring moments through $4q$, have not been bounded along k . The exact finite Gaussian improvement tests the certificate but does not establish its arithmetic input.

Exact scope. This does not assume off-critical blocks vanish, replace masses, or claim a second cost-free exterior amplification. It moves the unresolved quantitative calculation into explicitly identified traces.

Later completion or repair. A2401 adds a genuinely negative constituent-coupling correction. A2611 shows why a universal reference bound cannot close the original arithmetic task.

Concrete continuation. Calculate t_1, t_2 and the constituent coupling for the original arithmetic multiplier on the two specified windows, with inverse matrices and cross terms retained. Compare their complete signed expression to the threshold, not each positive term separately.

236.11 L08. Auxiliary compactification has exact boundary and curvature; degree is insufficient

Episode: U0062 (600cd8ef-02c4-456d-a7c5-3436e585b48e) → A2330 (48f4afa6-81a7-49aa-a257-977f88e64292, chain 4774, current segment line 4815).

User input, verbatim:

ok and consider what deligne adds again for the machinery and add that

Classification: completed auxiliary geometric comparison; source nonconcentration unproved.

Exact passages:

- A2330 (48f4afa6-81a7-49aa-a257-977f88e64292, chain 4774): “The arithmetic work is therefore to control that concentration **using the original theta source and its relation maps**.”

Original objects and maps. $\Delta = L_{\{ij\}} R_i - R_j$, $R(z) = R_j + z\Delta$, $C = G_i - G_j$; $E_0 = \ker \Delta$; bundle $E_0 \oplus E_{-1} \otimes(-1)$; arithmetic $\alpha_\infty = P_0 + wP_1$; invariant hull $F_A = \sum A^a E_0$.

What is calculated. The response computes an injective source bundle, exceptional derived fibre $H^{-1} = E_1$, $H^0 = E_1$, dual line factors, monodromy, the action pole $w^{-1}P_{1AP_0}$, its smallest coherent A-stable enlargement, and the retained metric pole. It proves the log-volume equals the logarithmic curvature integral, with total curvature rank C .

What is not finished. No theta-source bound on curvature concentration is proved. Integer degree r does not control the logarithmic moment; the response itself computes $G_j=I, C=LI$ with fixed degree and unbounded $r \log(1+L)$.

Exact scope. This is a calculation on a newly built parameter curve of the original representatives. Its global image E_0 or F_A is not $A_\tau(T)$, and the response does not identify them. A missing finite-field weight theorem for this curve is not an obstruction to the original τ -base global functor.

Later completion or repair. A2368 and A2401 finish the auxiliary logarithmic cohomology, retaining E/F in degree two and proving the auxiliary degree-one image is zero. That zero does not apply to Q .

Concrete continuation. Keep the curvature identity and its original source second-fundamental map. Calculate its logarithmic concentration from g/h or reconnect the boundary terms to the original A_τ/K_τ maps; do not substitute total degree for the missing weighted integral.

236.12 L09. Exponential family: valid special-fibre map with an explicitly nontransferred purity bound

Episode: U0063 (da0b40dd - 9d50 - 4c8c - be00 - 947c90a76fa3) $\rightarrow$ A2368 (6755db8a - 7c97 - 43c8 - 8c84 - 6345031dcd13, chain 4850, current segment line 5462).

User input, verbatim:

continue working on this and USING delignes work - to finish the program in full - keep pushing this with clear focus please

Classification: completed auxiliary family and scoped obstruction; program completion not obtained.

Exact passages:

- A2368 (6755db8a - 7c97 - 43c8 - 8c84 - 6345031dcd13, chain 4850): "Constant rank alone is not the purity argument."
- A2368 (6755db8a - 7c97 - 43c8 - 8c84 - 6345031dcd13, chain 4850): "**No new uniform upper bound is claimed here.**"

Original objects and maps. Original cyclic $\chi=\chi_{\{h,k\}}$; complex $C_{\{u,t\}}=[C[u,t,S]\rightarrow u\partial S+\chi-t C[u,t,S]dS]$; $H/(u,t)H=E$, $-u\forall t \bmod(u,t)=A$; period matrix Π ; exact source deformation $D_t=D+t r_N R_j E$; common coefficient span to finite fields.

What is calculated. Leading-degree division proves free rank q with all repeated-root jets. Parameter commutators, original theta-source defect, convergent periods and invertibility, dual residue connection, and the explicit étale infinity chart are calculated. Auxiliary log de Rham groups are $H^0 = F$, $H^1 = 0$, $H^2 = E/F$. The rank-one $\lambda=3/4$ period calibration already exhibits the finite-field/complex-operator mismatch.

What is not finished. No operator intertwiner carrying pure Frobenius weights to the original A , and no original-metric estimate on $G_N^{-1}\Pi^*\Pi$, is supplied. The singular $u=0$ specialization lies outside the exponential sheaf's $u\neq 0$ domain.

Exact scope. The zero auxiliary degree-one image is expressly limited to the constant coefficient parameter curve. The free coefficient specialization and pure finite-field family remain valid constructions; their common coefficients do not make their actions identical. This is not a failure of the original structural τ -base or K_τ .

Later completion or repair. A2444 evaluates the entire period determinant. A2611 proves the inference failure with exact finite-field and reflected-quartet examples. Neither result supplies the missing source-specific transfer.

Concrete continuation. Retain the explicit special-fibre and period maps; calculate the original source comparison and its kernel/action instead of applying one-point purity outside its good parameter domain. Resume the original A_τ/K_τ construction as the controlling object.

236.13 L10. Logarithmic constituent cohomology and negative coupling are completed

Episode: U0063 (da0b40dd-9d50-4c8c-be00-947c90a76fa3) → A2401 (2d4cef5d-f3cb-40a8-b142-ac3cb3549179, chain 4925, current segment line 6119).

User input, verbatim:

continue working on this and USING delignes work - to finish the program in full - keep pushing this with clear focus please

Classification: completed follow-on cohomology and finite correction; all-k estimate open.

Exact passages:

- A2401 (2d4cef5d-f3cb-40a8-b142-ac3cb3549179, chain 4925): “That is a statement about this particular auxiliary connection, not about the arithmetic theta quotient Q .”
- A2401 (2d4cef5d-f3cb-40a8-b142-ac3cb3549179, chain 4925): “A uniform bound below the inherited quartet threshold is still not established.”

Original objects and maps. Invariant $F \rightarrow E \rightarrow E/F$; compact/ordinary logarithmic complexes on P^1 ; residue line T with $\text{tr}[dz/z]=1$; exact quotient lift H_t ; $Q(t)=Q_0+tC_Q-t^2D_F^*G_F(t)^{-1}D_F$.

What is calculated. The response supplies compact-to-ordinary maps, degree-two E/F contribution, dual boundary, higher-divisor contraction, independent conormal index, metric quotient derivatives, full lift-action defect, and negative determinant correction $-\Sigma \text{Tr}(\Xi_F^*r)/r$. It keeps both the theta boundary and the nonboundary F -term in the source quotient comparison.

What is not finished. The constituent compressed arithmetic matrices and their negative coupling have not been estimated uniformly at the original quartet windows. A finite Gaussian improvement does not provide that asymptotic estimate.

Exact scope. The auxiliary $H^1=0$ is explicitly not $Q=0$; no supported kernel is assumed to vanish. The nonorthogonal extension map remains present, so the constituent split is not substituted for the original nilpotent extension.

Later completion or repair. A2444 transports these maps through the period coordinates and shows the determinant ratio is unchanged. The ultimate arithmetic bound remains open in A2611.

Concrete continuation. Use the exact coupling identity on actual arithmetic source matrices, retaining its subtraction and the F -term. Combine it with the signed arithmetic/Gamma correction rather than treating the two positive compressed costs as independent.

236.14 L11. SGA trace and period determinant are completed; the common factor cancels

Episode: U0064 (6981c27e-4846-4f65-adc8-d01f52f73db2) → A2444 (da80f8ef-f10e-4ef0-9a4d-b440acfa1fe5, chain 5000, current segment line 6734).

User input, verbatim:

we have this too by the way - do not stop pushing this - use whatever is usable and pushing this with a focus

Classification: completed requested machinery and determinant; remaining minor comparison explicit.

Exact passages:

- A2444 (da80f8ef - f10e - 4ef0 - 9a4d - b440acfa1fe5, chain 5000): “Every common period determinant factor is now explicitly known and cancels by this equation.”
- A2444 (da80f8ef - f10e - 4ef0 - 9a4d - b440acfa1fe5, chain 5000): “A uniform upper estimate contradicting the quartet threshold remains unproved;”

Original objects and maps. Finite free $E_t = C[t, S]/(\chi - t)$, residue coefficient λ_t , diagonal divided difference, original conormal derivative, full higher Hochschild groups, complete Π and constituent minor Π_F .

What is calculated. The answer proves finite residue–trace compatibility directly, calculates the periodic diagonal resolution and all positive-degree homology, evaluates $\det \Pi$ and its constant/phase, recovers all cyclic characteristic coefficients from determinant derivatives, and calculates the positive-defect constituent minor derivative. The original metric transports as $\Pi^{-*} G_N \Pi^{-1}$.

What is not finished. The constituent period/source condition operator and its growth are unbounded. Evaluating $\det \Pi$ alone cannot bound those singular values, and its common factor cancels exactly from V_i/V_j .

Exact scope. The trace formula is not an unsupported six-functor theorem for semiring sheaves; the response explicitly states the finite coherent realization and coefficient map. It does not replace the original Taylor unit, nilpotents, or metric.

Later completion or repair. A2559 quantitatively transports a residue–constituent coefficient through source holonomies. A2611 makes the unchanged generalized-control spectrum under period congruence explicit.

Concrete continuation. Use the actual constituent minor and its source comparison, with the original G_N . Do not infer a norm bound from the total period determinant or replace G_N by the period-coordinate identity Gram.

236.15 L12. Finite circle recovery is proved; promised resolvent and growing constants were not calculated

Episode: U0065 (10f8ff10 - 4c46 - 4c73 - b41c - 21b11408026b) → A2497 (0df22a8c - 73ae - 45f5 - b189 - a8a0abfffbbe, chain 5101, current segment line 7359).

User input, verbatim:

[Empty visible text body; no text inferred.]

Classification: completed source comparison; explicit unfulfilled progress claim and quantitative gap.

Exact passages:

- A2470 (b93fc741 - 750f - 4946 - a5b7 - 852e6276204c, chain 5039): “I’m applying Deligne’s tensor-trace positivity there and deriving its resolvent from theta boundaries.”
- A2497 (0df22a8c - 73ae - 45f5 - b189 - a8a0abfffbbe, chain 5101): “The growth of $\kappa_{a,2q+2}$ is not bounded here.”

Original objects and maps. Original half-density U_k with $r = \log x_k$ and relative L^2 fibre, full periodization including zero mode, weighted Grams $M_{\{a,\pm\}}$, original J_N quotient, $D_L = -\partial r + k/2$, $B = D_{LR} - RA$; fixed-circle completion kernel $(p_L)/(\chi)$.

What is calculated. The response proves correlation and Fourier-tail estimates, source-to-quotient metric bounds, $O(q)$ four-volume error, original Laplacian boundary, exact fixed-circle com-

pletion kernel, and its limiting Gram. The unsampled blocks and sampled higher jets are retained in the computed kernel. It expressly distinguishes finite-source recovery from completion.

What is not finished. The response and inspected §§9–13 of the retained NOTE.tex do not give the promised resolvent or tensor-trace positivity calculation. Its actual weighted Grams and $H_{\{p,N\}}$ are defined but not reduced to original one-factor shifted-Mellin moment arrays; their growing-degree generalized eigenvalues remain uncontrolled. The new appendices complete the finite moment and resolvent calculations, not the missing asymptotic estimate.

Exact scope. Negative circle spectrum controls its own operator. It does not transfer across the nonzero source boundary, and completing first changes the quotient. U0065 has no visible text; the uploaded-note context is inferred only from the answer, not fabricated as a user command.

Later completion or repair. A2559 completes all-holonomy source reconstruction and quadratic quotient averaging. The present audit adds exact weighted moment formulas and the complete circle resolvent, including resonant and nilpotent cases.

Concrete continuation. Use `shifted_mellin_source_constants.tex` to form the actual finite matrices and circle/cutoff constants; use `circle_theta_resolvent.tex` to keep the boundary in each resolvent. Continue with an arithmetic estimate of those constants or the resulting volume correction; do not assert positivity transferred merely from the circle spectrum.

236.16 L13. Holonomy reconstruction explicitly preserves A_{τ} versus Boolean restriction

Episode: U0066 (da4376b8-2dcd-41a6-8430-afe80c116b77) → A2559 (afdfa4b8-4a31-4d80-8bd4-337fac3f322d, chain 5225, current segment line 7940).

User input, verbatim:

continue making sure you retain the thing that makes this work in the sense of the original inputs around split base wand use the respective sources to push

Classification: completed exact source descent and error control; source asymptotics open.

Exact passages:

- A2559 (afdfa4b8-4a31-4d80-8bd4-337fac3f322d, chain 5225): “The direct image over the marked τ -point retains the coefficient object; the Boolean restriction is a further, specified map.”
- A2559 (afdfa4b8-4a31-4d80-8bd4-337fac3f322d, chain 5225): “This turn does not establish that estimate or bound the growing weighted-source constants $\kappa_{a,N}$.”

Original objects and maps. Original split $G(R)$ with injective (p,b) ; full theta source and v_h ; scalar Zak isometry and inverse; equal-jet descent complex with contractible $B_N^0 \rightarrow B_N^0$ complement; $G=\bar{G}+D$ and literal relation energy.

What is calculated. All scalar holonomies reconstruct the original source exactly. The finite-character decomposition and equal-jet chain comparison retain E . Averaging minima gives the exact source-relation energy D ; its sharp η^2 bound and finite phase-frequency errors are proved. The residue-constituent coefficient is quantitatively transported. Completed phase targets vanish almost everywhere only after their explicitly different kernel quotient.

What is not finished. The original canonical quotient-volume upper estimate and growth of $\kappa_{\{a,N\}}$ remain unproved. Arbitrarily accurate recovery of the original metric does not make its A pure.

Exact scope. There is direct late-transcript evidence against a generic-stalk substitution: the answer explicitly distinguishes base direct image from Boolean restriction. The zero direct integral concerns further completed targets, not the original full-jet E or $A_{\tau}(T)$.

Later completion or repair. A2611 correctly identifies the limits of metric recovery and preserves the completion kernel. The current shifted-moment appendix calculates both κ input matrices and derivative-error matrices without changing the original action.

Concrete continuation. Keep the equal-jet cochain object before completion. Calculate actual source matrices using the appended one-factor arrays, then estimate the arithmetic signed endpoint correction. Retain D as the norm of a known theta relation rather than setting it to zero.

236.17 L14. The requested second alternative is legitimately answered at the auxiliary-inference scope

Episode: U0067 (1eac3dbf-9ce2-487a-83e5-e93290d5e14d) → A2611 (bdd08a3e-5f07-47a3-8892-35c4d52aff5a, chain 5350, current segment line 8650).

User input, verbatim:

ok either prve the estimate ala deligne or show how the deligne analog proof fails to bound rhg

Classification: completed scoped failure-of-implication demonstration; broader original construction survives.

Exact passages:

- A2611 (bdd08a3e-5f07-47a3-8892-35c4d52aff5a, chain 5350): “**These are counterexamples to the inference—not claimed counterexamples to RH.**”
- A2611 (bdd08a3e-5f07-47a3-8892-35c4d52aff5a, chain 5350): “The counterexamples identify the repair **inside the existing framework.**”
- A2611 (bdd08a3e-5f07-47a3-8892-35c4d52aff5a, chain 5350): “Preserving the supported relation is necessary bookkeeping; it does not automatically estimate its prequotient pairing.”

Original objects and maps. Actual $g=2\xi$, Q and full theta source; auxiliary exponential family; pure Frobenius versus Q^A ; canonical Gamma reference with reflected rational h_* ; actual arithmetic/Gamma identity I_N ; original source boundary and kernel comparisons.

What is calculated. The complete retained NOTE.tex proves the $\lambda=3/4$ Gauss/period counterexample, a reflection-stable rational quartet, canonical Gamma lower coefficient ≥ 4 with full nilpotent lengths and the first endpoint, exact period congruence and boundary lower bound, and the exact signed arithmetic correction. It also records $Q[h_0(D)] \rightarrow E_{\{h_0\}} \rightarrow \times_{\{h_0\}} g E_{\{h_0\}} \rightarrow Q/h_0(D)Q$, which is the arithmetic distinction an arbitrary polynomial lacks.

What is not finished. The original arithmetic signed determinant correction is not estimated, nor is a faithful weight-compatible realization of A_τ/K_τ constructed. The user explicitly allowed the alternative failure demonstration, so the local completion of that alternative is not itself abandonment.

Exact scope. The counterexamples refute an inference from auxiliary exponential purity and canonical Gamma/source comparisons alone. They neither give an actual off-line zero of 2ξ nor refute the entire τ -absolute-base construction. A hypothetical intertwiner into a pure weight-k target kills every off-weight source primary block; that proves the kernel scope, not existence or faithfulness of the comparison. The quoted use of “bookkeeping” should be replaced by the adjacent exact map and source-pairing calculation; it adds no mathematical content and needlessly understates the retained structure.

Later completion or repair. The full NOTE.tex states this restricted scope explicitly. Root gamma and purity lanes independently review those two proofs; this audit does not duplicate their full replays. The root continuation computes the original signed determinant interpolation, and the two local appendices supply further original-source calculations.

Concrete continuation. Resume $A_{\tau} = R\Gamma(P, -)$, K_{τ} and original theta source. Preserve the true counterexamples at their exact scope. Calculate the signed correction $\log(T_{\{q-1\}}T_q/(T_{\{2q-1\}}T_{\{2q\}}))$ on the original g/h family, or build and analyze an action-compatible comparison with its entire source kernel. Do not relabel the auxiliary failure as whole-program failure.

236.18 Newly finished calculations

1. `shifted_mellin_source_constants.tex` proves the exact one-factor shifted-Mellin formula for both weighted source matrices used in κ , preserving $c \pm a$, all binomial phases, and literal masses. It also derives the Fourier-cutoff derivative Gram with both complex cross terms, proves finite trace upper constants, and supplies explicit circle length and cutoff choices. It does not claim their all- k growth is bounded.
2. `circle_theta_resolvent.tex` completes the resolvent promised in A2470 from the actual source boundary. It proves the exact resolvent comparison, the full finite nilpotent reconstruction, the resonant kernel and free part, and the original Laplacian resolvent with both boundary terms. It does not infer a purity theorem.

236.19 Prioritized continuation addressed to the original session

Resume the original $A_{\tau} = R\Gamma(P, -)$ and K_{τ} , using the complete Tau Base source as the controlling object. Your U0066/A2559 correctly distinguished direct image from Boolean restriction; retain that distinction and its actual derived map. Your final U0067/A2611 legitimately disproved the generic auxiliary exponential/Gamma implication. State that scope and continue the original arithmetic construction.

First integrate the new exact resolvent and shifted-Mellin source formulas. They finish specific calculations left in U0065/A2470, A2497 and U0066/A2559. Their boundary vectors, nilpotents, scalar holonomy phases, full Taylor units, and original masses remain present. Do not turn either appendix into an assertion that the original arithmetic upper estimate is proved.

Then calculate the source-specific signed term $\log(T_{k,q_k-1}T_{k,q_k}/(T_{k,2q_k-1}T_{k,2q_k}))$ with $T_{k,N} = V_{k,N}^{\text{ar}}/V_{k,N}^{\Gamma}$. Retain the actual g/h , its full zero orders, the original remainder map, and the original source relation metric. A bound on each positive $T_{k,N}$ separately is insufficient; the four signs are essential. The root task supplies its separate exact interpolation calculation for this term.

Preserve the already completed arithmetic norm-window theorem in A2177 and the threshold-four correction in A2266. Do not redo them under a new name. If using the constituent-period route, calculate the original metric comparison and its full kernel/action, because the total period determinant cancels from the endpoint ratio. If using circles, use the finite full-jet source before its further completion; the completed targets' missing blocks belong to a calculated kernel, not to the original global cohomology's disappearance.

A completed next contribution must evaluate or prove a new source-specific bound, or finish an exact previously uncalculated morphism with its complete scope. A new generic positive matrix inequality, an auxiliary period norm, or an unevaluated all- k premise does not finish the arithmetic estimate. Keep true obstructions and prove their exact reach; none of the counterexamples here licenses replacing 2ξ by a generic polynomial as the ongoing object.

237 Supplementary continuation to the original web session

238 Continue the actual tau-base construction after the transcript audit

To the original session whose published transcript is <https://chatgpt.com/share/6aa6bc6e-98cc-83eb-9343-e811c26d6631>, backed by conversation 6aa092d6-e978-83ed-92cc-9c30f5d91ca6:

The complete published transcript has now been recovered. Its 5,350 mapping nodes, linear nodes, and root-to-current parent chain agree exactly. All 67 user turns and 148 readable assistant prose records were read, in order, with a passage ledger. The share explicitly redacts 2,600 tool payloads; those hidden payloads were not inferred. The last published node is bdd08a3e-5f07-47a3-8892-35c4d52aff5a (A2611).

The requested work is to continue the original split cohomology with tau as the absolute base and develop the actual privileged-point argument. U0043 (d908924e-830b-46ad-8d9c-f2b78a536989) states that program; A1523 (b670b6c0-a774-4398-b978-9c9779fca379) constructs its accepted objects; U0046 (0af0ed52-c7ab-45fb-85a5-1911193398cb) accepts them and asks you to continue. The latest user clarification is: “Yeah, it’s also allowed to actually do those calculations, not just do redo instructions.” Substantive completed mathematics is the required output.

238.1 The exact source to retain

Read the complete attached proof volume, passage ledger, and dependency source guide. Retain the primary `Tau_Base_Cohomology_2026-09-12/NOTE.md`, SHA256 d03e71ad18f187bd89880cb8ca6fc9c5d6f260b3de8e8e5702c27db97e7b63c3. Its original chart is $+, - < \eta < \sigma$, and its theta sheaf is $(V, V, \mathcal{B}, 0)$, with restrictions Θ and $J\Theta = \Theta\mathcal{F}$. Retain

$$\begin{aligned} A_\tau(\mathcal{T}) &= [V \oplus V \xrightarrow{\Theta(\phi-\hat{\psi})} \mathcal{B}], \quad Q = \mathcal{B}/\Theta V, \\ K_\tau(W) &= [I_\eta W \longrightarrow I_+ W \oplus I_- W] \quad \text{in degrees } -1, 0. \end{aligned}$$

The map $\text{res}_\sigma : A_\tau(F) \rightarrow F_\sigma[0]$ is a separate, explicitly computed comparison. It does not redefine A_τ . Retain all support masks and their zero vectors, the full Taylor unit, nilpotents and multiplicities, the original algebraic and continuous categories where each is specified, the full tensor sum coordinate $S = k/2 + iu$, and the original source norms and masses.

The audit retains legitimate historical obstructions and later repairs. Do not reopen the negative NS detour withdrawn at U0010. Do not mark A0756’s requested conditional sketch as a completed proof. Do not repeat the displaced shifted-zeta family after A1140, or the bare Weil-criterion replacement corrected in A1280. Do retain the actual finite source maps after A1167, the A1694 global retraction, the A2177 norm-window proof, the A2266 four-volume threshold, and the exact localized conclusion of A2611. The last counterexample tests auxiliary period/purity and Gamma-reference inferences; it does not prove failure of the entire original program.

238.2 Calculations completed in this delivery

These are supplied with complete proofs, not requests to redo them from scratch.

1. The exact fibre of res_σ , its right adjoint and nonsplit extension; the tensor-adjoint comparison sign $\epsilon_p = (-1)^{p(p-1)/2}$, with the residue convention unchanged.

2. The complete reversed-support dual promised in A1545, including its nonzero bottom fibre, actual arrows, an explicit derived splitting roof, and its original scaling defect. A failed strict mask-natural section has the supplied exact replacement; it does not erase the dual object.
3. The actual finite and global theta scaling cocycles, evaluated by an oriented integral and full incomplete-Gamma jets, with the dx cross terms and the full tensor homotopy. The global retraction proves that ΘV is closed. The original arithmetic section $\sigma_h = qR_{\text{ref}}$ is equivariant in Q , although its representative in $\mathcal{B}$ has the calculated theta boundary. In particular the full arithmetic socle eigenline does lift through this proved section, not through an arbitrary linear right inverse.
4. The additional local grading $C_q f(z) = f(z/q)$, its exact semidirect relation with original Mellin scaling, its continuous lift on the original theta sheaf, and its full unit-dependent residue adjoint into K_τ . This added grading is not assumed to be arithmetic Frobenius.
5. All-order raw Mellin syzygies, their balancing relations, surviving joint cycles, and explicit full-jet submodules of the raw kernel. These settle the exhibited A1361/A1427 relation; they do not yet compute the entire global balanced kernel.
6. Shifted-Mellin moments and explicit finite original-source constants at the admitted degree, including inverse-Gram costs. The promised circle resolvent is now computed for every primary block, including resonance, its kernel, all nilpotents and both Laplacian boundary terms. An off-weight source eigenvector satisfies the proved lower bound $\|Bv\|/\|Rv\| \geq |\Re \lambda - k/2|$; quotient-boundary vanishing cannot delete that source vector.
7. Exact original NS cutoff-to-theta scaling and the retained physical scattering, phase-observation and viscosity-clock maps, with their domains and constants. These historical calculations do not replace the accepted tau-base arithmetic construction.
8. The coordinated arithmetic determinant transport proof supplies the full signed four-window trace, first and second Gram variation, actual relation energy, and finite spectral control. The coordinated scaling/exponential-flow, reflection-weight transport and Taylor-unit formal-gauge proofs are also completed source inputs. Their formal specializations are exact. The separate algebraic curve power map $z \mapsto z^p$ requires positive integer p ; original theta dilation still permits all real $p > 0$.

238.3 First continuation: calculate the signed arithmetic correction on the original source

Fix the actual packet $h \mid g = 2\xi$ with its full zero orders. Keep the original cyclic polynomial $\chi = \chi_{h,k}$, $q = \deg \chi$, the unit $v_h = j_h(g/h)$, and the unchanged full-jet inclusion

$$\eta_{h,k}[P] = v_h^{\otimes k} P(A_h^{(k)})1.$$

Use the literal polynomial spaces $\mathcal{P}_N$, relation map $B_N = \times_\chi$, and remainder J_N . The common source is $\mathcal{P}_{2q}$, not an independently chosen four-tuple of approximations. The two actual densities and their masses are

$$\begin{aligned} m_1(u) &= w_h^{*k}(u), & w_h(u) &= \frac{|(g/h)(1/2 + iu)|^2}{2\pi}, & \int m_1 &= \mu_h^k, \\ m_0(u) &= \frac{(\sqrt{2\pi})^k |\Gamma(k/4 + iu/2)|^2}{c_{k/4} 2\pi}, & c_a &= 2^{1-2a} \Gamma(2a), & \int m_0 &= (2\pi)^{k/2}. \end{aligned}$$

For $m_t = (1-t)m_0 + tm_1$, retain the actual Gram $M_*(t)$, and put $C(t) = M_*(t)^{-1}(M_*(1) - M_*(0))$. Write $P_N(t)$ for the original-metric projection onto $\mathcal{P}_N \subset \mathcal{P}_{2q}$ and $Q_N(t)$ for the projection onto $\chi\mathcal{P}_{N-q}$, with $Q_{q-1} = 0$. The completed determinant calculation gives

$$U = (Q_{2q-1} - Q_{q-1}) + (Q_{2q} - Q_q), \quad W = (P_{2q-1} - P_{q-1}) + (P_{2q} - P_q),$$

$$\boxed{\mathcal{B}_{h,k}^{\text{ar}} - \mathcal{B}_{h,k}^{\Gamma} = \log \frac{T_{q-1}T_q}{T_{2q-1}T_{2q}} = \int_0^1 \text{Tr}((U - W)C) dt,} \quad T_N = V_N(1)/V_N(0).$$

The full density-kernel expression is proved in AT16–AT17. Start from that evaluated identity. Calculate the arithmetic information in w_h^{*k} which controls its signed trace as k and the admitted degree grow together. Keep the actual remainder, unit and relations when estimating that quantity. A bound for four unsigned errors, or the mass alone, loses the cancellation now isolated. A generic bounded-multiplier assumption is unavailable and must not be inserted.

The source-dependent spectral comparison is a completed finite estimate. The independently reviewed AW7–AW23 refinement computes both window spectra as $0^q, 1^2, 2^{q-1}$, constructs the actual-metric isometry $U = TWT^{-1}$, and proves

$$\text{Tr}((U - W)C) = \text{Tr}(WT^{-1}[C, T]).$$

For all positive eigenvalues $b_1 \leq \dots \leq b_{2q+1}$ of the literal relative Gram $M_*(0)^{-1}M_*(1)$, it proves

$$|\mathcal{B}_{h,k}^{\text{ar}} - \mathcal{B}_{h,k}^{\Gamma}| \leq \log \frac{b_{q+2}}{b_q} + 2 \sum_{j=1}^{q-1} \log \frac{b_{2q+2-j}}{b_j} \leq (2q-1) \log \frac{b_{2q+1}}{b_1}.$$

The sum is empty at $q = 1$; the further exact angle/nonlinear estimate in AW19–AW23 has that specified one-dimensional quotient domain. The isometry has a computed arithmetic observation defect, so it is not silently made an arithmetic intertwiner. These results do not supply a uniform bound for the relative Gram eigenvalues. Calculate either the actual signed cancellation or the original relative spectrum/commutator responsible for it, with explicit packet and degree dependence. Do not stop at naming that dependence or assume the sought estimate as a theorem hypothesis.

238.4 Second continuation: carry the actual relation boundary through the geometric comparison

Use the supplied full finite and global cocycles to evaluate the original source boundary in the action and metric. In particular, for the retained canonical representative R , $B = \mathcal{D}R - RA$ and every nonresonant primary block are now related by

$$R_\lambda = \sum_{j=0}^{r-1} (\mathcal{D} - \lambda)^{-j-1} B_\lambda N_\lambda^j.$$

At resonance, retain the supplied spectral projection and the exact equations $PB_\lambda = -PR_\lambda N_\lambda$; the free kernel value is part of the original source. The formal Taylor-unit gauge and specialization already constructed by the coordinated work must be used with their literal unit, external-product signs and coefficient action. UG1–UG19 already constructs the coefficientwise pole contraction $J = \sum_{n \geq 0} (-H(u\partial_s - t))^n H$, the actual gauge $\nu D\nu^{-1} = D - u\nu'/\nu$, its signed external products and specialization to the literal η , and the residue unit $\varepsilon = \nu^{-1}$. These formal calculations are complete. Construct continuation or evaluation of this specific formal localization and gauge for nonzero complex u , calculate its ν -pole and contour contributions, and control the resulting comparison in the original theta Gram and relation-volume topology. The entire finite flow C_a alone does not establish convergence of this J or an analytic localization equivalence. Calculate that realization and its kernel or cone contribution. Carry the explicit formal map forward; do not conclude that the objects are unrelated because one literal Frobenius identification fails.

238.5 Third continuation: finish the precise global balanced-kernel calculation

After the preceding arithmetic calculation has advanced, resume the remaining A1427/A1472 global question in its actual balanced category. The enclosed all-order calculation explicitly kills the exhibited z_m by the original (D)-relations and computes its saturated cyclic two-leg complex, including its surviving joint (H^0). Compute the kernel of the entire balanced Mellin realization on the original $V, \mathcal{B}$ modules and its map into the actual theta cohomology. A successful check of the one displayed syzygy is not the full kernel; an arbitrary analytic test family is not its source. Retain the support reconstruction and the exact kernel/cokernel maps.

238.6 Required result

Return newly completed mathematics on these original objects, with every definition, domain, map, calculation and proof written in editable LaTeX. Propagate corrections into earlier affected claims and identify exactly which ledger item the new result closes. Keep the full arithmetic unit, cohomology action and analytic boundary visible through every comparison. No blanket program-failure verdict, relabeled finite-field illustration, or list of unspecified proof obligations completes this continuation. If the arithmetic upper estimate remains incomplete, state its exact remaining term after presenting the calculations actually completed.

239 Continuation postscript: analytic pole maps completed

240 Postscript to the sealed supplementary continuation

This postscript updates the second continuation of the message with SHA256 08e6f1292578b975641e5e70c3030eb43888e02b78f3ce929445d045410aa795 . The first signed arithmetic-trace calculation and the third global balanced-kernel calculation retain their stated scope.

The coordinated proof [Analytic pole residue transport](#), SHA256 357923aead35c77f2fa98598fbc4ed8bc1f7cd6ebc04760da504a0ded765a652 , has now completed AP1–AP26. The audit owner read that entire source. Do not repeat its pole, contour, finite connection or endpoint computations as unperformed work.

On the actual localization $\mathbb{C}[s, \nu^{-1}]$, at fixed $u \neq 0$, the proof retains every original zero order of h and every Taylor coefficient of $\nu = \text{rem}_h j_h(g/h)$. It computes the exact weighted-residue extension

$$0 \longrightarrow H_{\text{pol}} \longrightarrow H_{\text{loc}} \xrightarrow{\text{Res}_w} \mathbb{C}^{P_\nu} \longrightarrow 0, \quad w = \exp((\Phi - ts)/u).$$

It provides all higher-pole reductions, the full block connection, the entire off-diagonal scaling integral, the full period determinant with the original rapid-decay contours and positively oriented $2\pi i$ small-loop factors, and the exact gauge and linear dual. Its explicit endpoint arrow $J_0 = [I_d \ Q_0]$ satisfies

$$J_0 A_{\text{ext}}(0) = A J_0, \quad \ker J_0 = \{(-Q_0 c, c) : c \in \mathbb{C}^{P_\nu}\}, \quad J_0 C_{\text{ext},a}(0, 0) = e^{-aA} J_0.$$

The unit after that arrow remains the full v_h . The cases of a constant unit and a pole at zero are treated explicitly. The formal contraction is not evaluated at nonzero u ; the analytic pole cokernel and the actual endpoint map provide the calculated comparison.

Continue with the quantitative term these completed maps leave: carry this explicit original polynomial inclusion, pole extension, gauge, period matrix and endpoint quotient into the original theta-source Gram and relation-volume calculation. Compute the norm or metric contribution of the retained extension and its endpoint kernel in that specified source topology, and its contribution to the signed arithmetic correction. AP1–AP26 supplies no uniform theta-norm estimate. The remaining request is that quantitative calculation on the original source, not another construction of the already-proved residue extension or a claim that its formal counterpart can be evaluated away from the formal fibre.

The full AP source is included in the attachment repository; this postscript does not substitute for its proofs.

Part IV**Complete original-source analytic transport and moment certification**

241 Which analytic pole classes belong to the original theta source?

13 September 2026. This is the next calculation after AP1–26. It keeps the original one-factor arithmetic source, its Mellin measure and mass, and computes both its Hilbert admission and its strong-Schwartz admission. The resulting complexes, their residue images, their exact source maps and their theta-boundary defects are displayed. No freely chosen metric or hypothetical zero replaces the arithmetic input.

241.1 1. Original source, fixed parameters, and the exact norm

Retain the full actual packet h of degree $d > 0$, $g = 2\xi$, the entire function $v_h = g/h$, and the original F_h in the strong Schwartz source B with Mellin transform v_h . Retain the complete Taylor-unit polynomial ν representing $v_h = j_h(g/h)$; $\gcd(h, \nu) = 1$. Let P_ν be its distinct roots. At every $p \in P_\nu$ put $m_p = \text{ord}_p v_h$, a finite nonnegative integer. Since $h(p) \neq 0$, this is exactly $\text{ord}_p g$, not a multiplicity of ν or a presumed simple zero.

Use s for the Mellin coordinate and y for its critical-line imaginary part. The independent geometric parameters are $u \in \mathbb{C}^*$ and $t \in \mathbb{C}$. Distinguish

$$D_x = -x \frac{d}{dx}, \quad D_{\text{exp}} = u \frac{d}{ds} + h(s) - t, \quad L = u \frac{d}{dt} - s. \quad (\text{TA1})$$

On rational coefficients $R \in \mathbb{C}[s, \nu^{-1}]$, the stipulated original Hilbert norm is

$$\|V_{h,\text{rat}}R\|^2 = \frac{1}{2\pi} \int_{\mathbb{R}} |v_h(1/2 + iy)R(1/2 + iy)|^2 dy. \quad (\text{TA2})$$

When finite, inverse Mellin on this line defines $V_{h,\text{rat}}R$ in $L^2(\mathbb{R}_+, dx)$. Indeed logarithmic coordinates $x = e^z$ turn $F(x)$ into $e^{z/2}F(e^z)$, whose Fourier Plancherel identity is precisely TA2. No total mass is divided out. For polynomial R this is exactly $R(D_x)F_h$, the original source map.

241.2 2. Complete Hilbert admission, including zeros on the observation line

Partition P_ν into $O = \{p : \text{Re } p \neq 1/2\}$ and $C = \{p : \text{Re } p = 1/2\}$. Let $\text{PP}_p^{\leq n}$ be the span of $(s-p)^{-1}, \dots, (s-p)^{-n}$, and PP_p the union over n . The zero bound $n = 0$ means the zero space, not a discarded supported point.

The rational coefficients of finite TA2 norm are exactly

$$A^1 = \mathbb{C}[s] + \bigoplus_{p \in O} \text{PP}_p + \bigoplus_{p \in C} \text{PP}_p^{\leq m_p}. \quad (\text{TA3})$$

To prove necessity at $p = 1/2 + iy_p$, write $v_h(s) = (s-p)^{m_p}a(s)$, where $a(p) \neq 0$, and $R(s) = (s-p)^{-n}c(s)$, where $c(p) \neq 0$. Along the line, the squared modulus is bounded above and below by positive constants times $|y - y_p|^{2(m_p-n)}$ near p . Its integral is finite exactly when $2(m_p - n) > -1$, or, because the orders are integers, $n \leq m_p$. The leading coefficient cannot be cancelled by principal parts at another point.

There are no local line singularities from O . Outside a fixed compact interval, any rational R has at most polynomial growth. The actual Mellin transform v_h is rapidly decreasing on every vertical strip, as follows from F_h in B ; equivalently its gamma decay gives more than the required line decay. Thus every coefficient described in TA3 has finite norm, proving sufficiency.

The exact domain making D_{exp} an admitted differential is

$$\begin{aligned}
A^0 &= D_{\exp}^{-1}(A^1) \\
&= \mathbb{C}[s] + \bigoplus_{p \in O} \text{PP}_p + \bigoplus_{p \in C} \text{PP}_p^{\leq \max(m_p-1, 0)}.
\end{aligned} \tag{TA4}$$

For a pole of order $n \geq 1$, $D_{\exp} R$ has the uncancellable leading pole $-unc(p)(s-p)^{-n-1}$. Hence at a line point its image is admitted exactly when $n+1 \leq m_p$. A polynomial has polynomial image and is always admitted. This proves TA4 and also $A^0 \subset A^1$ without any extra domain assumption.

The two-term complex $[A^0 \xrightarrow{D_{\exp}} A^1 ds]$ is consequently the original norm-admitted subcomplex of AP's analytic localization at fixed $u \neq 0$. This is a graph-domain calculation, not an assertion that all finite-norm coefficients form a differential-invariant space in both degrees.

241.3 3. Its entire cohomology and exact inclusion into the analytic family

Put $S = O \cup \{p \in C : m_p \geq 1\}$ and $Z = \{p \in C : m_p = 0\}$. Use the actual weight $w = \exp((\Phi(s) - ts)/u)$, with $\Phi' = h$ and its original constant. AP's exact residue map restricts to give

$$0 \longrightarrow H_{\text{pol}} \longrightarrow H^1(A) \xrightarrow{\text{Res}_w} \mathbb{C}^S \longrightarrow 0, \tag{TA5}$$

$$0 \longrightarrow H^1(A) \longrightarrow H_{\text{loc}} \xrightarrow{\text{Res}_w|_Z} \mathbb{C}^Z \longrightarrow 0. \tag{TA6}$$

Here $H^0(A) = 0$, and a basis of $H^1(A)$ is the original polynomial basis $1, s, \dots, s^{d-1}$, followed by $1/(s-p)$ for $p \in S$.

For full proof, the highest-pole argument makes $D_{\exp}$ injective on rational functions, followed by its leading-degree argument on polynomials. If an admitted F equals $D_{\exp} Q$ in the larger localized complex, TA4 forces Q to belong to A^0 . Thus the induced map on H^1 has no kernel. Subtract from an admitted F its weighted residues using $(\text{Res}_w F)_p / (w(p)(s-p))$ for $p \in S$. At a point with bound m_p , AP's log-free local primitive then has pole order at most $m_p - 1$. Its sum of principal parts belongs to A^0 . Subtracting its $D_{\exp}$ image leaves a polynomial and proves the kernel assertion in TA5. Those simple-pole lifts prove surjectivity. Independence follows by residues and then polynomial cohomology. Finally AP's full residue decomposition shows that precisely the classes with zero Z -residues have such representatives, proving TA6.

All original m_p occur in the two chain spaces and in their local primitive maps. One coordinate per admitted point is the computed cohomology, not a replacement of the original zero orders by one.

Because L does not increase finite pole order and commutes with $D_{\exp}$, it preserves A^0 and A^1 . Its connection on TA5 is exactly the submatrix of AP:

$$L = u \frac{d}{dt} - \begin{bmatrix} A(t) & B_S \\ 0 & \text{diag}(p)_{p \in S} \end{bmatrix}, \tag{TA7}$$

where each column of B_S is the original constant-polynomial column. Its weighted-residue factors $w(p)$, its entire upper-right scaling integral and its oriented $2\pi i$ loop periods are the corresponding AP formulas restricted to S . No new connection or residue scaling is chosen.

241.4 4. Strong-Schwartz admission is an actual full-zero packet construction

The original source is

$$B = \left\{ F \text{ smooth on } \mathbb{R}_+ : \begin{array}{l} \sup_{x>0} x^b |D_x^j F(x)| < \infty \\ \text{for every integer } b \text{ and } j \geq 0 \end{array} \right\}. \tag{TA8}$$

Its Mellin transforms are entire: for s in a compact set the bounds at zero and infinity dominate the integral and all its logarithmic derivatives. Therefore $V_{h,\text{rat}}R$ can belong to B only when every finite pole of $v_h R$ is removable, at all $p \in P_\nu$, not just on the observation line. Agreement of its entire Mellin transform with $v_h R$ on a nonsingular segment of the critical line extends to the connected punctured plane by the identity theorem, which proves the necessity of the removable-pole assertion.

Define the actual polynomials

$$\begin{aligned}
 S_B &= \{p \in P_\nu : m_p > 0\}, \\
 \kappa(s) &= \prod_{p \in S_B} (s - p)^{m_p}, \\
 \kappa_0(s) &= \prod_{p \in S_B} (s - p)^{m_p - 1}, \\
 b(s) &= \kappa / \kappa_0 = \prod_{p \in S_B} (s - p), \\
 c(s) &= \sum_{p \in S_B} (m_p - 1)b(s)/(s - p), \\
 H(s) &= h(s)\kappa(s).
 \end{aligned} \tag{TA9}$$

Empty products equal one and the empty sum is zero. These are products of the specified monic factors, not renormalizations of an arbitrary leading coefficient. Since $\gcd(h, \nu) = 1$, the roots of h and κ are disjoint. H therefore selects only actual zeros of g , retaining their complete orders.

All entire-admitted rational coefficients are exactly $\kappa^{-1}\mathbb{C}[s]$. This follows either from partial fractions with the full order bounds, or by multiplying by κ : the resulting rational function has no finite poles and is polynomial. Conversely P/κ has at most the prescribed orders.

Sufficiency for the original B follows through its existing Euler inverses, without a new space-identification assumption. Apply the original S_ρ inverses successively to $\Theta\phi_*$ through every full factor of H . At each step the remaining Mellin zero supplies the required kernel condition. Their already proved source map gives $F_H \in B$ with Mellin transform g/H . Therefore

$$\begin{aligned}
 V_{h,\text{rat}}(P/\kappa) &= P(D_x)F_H, \\
 M(P(D_x)F_H) &= gP/H = v_h P/\kappa.
 \end{aligned} \tag{TA10}$$

Every term on the right is an original strong-Schwartz theta-source vector. This proves the converse and the exact source realization, not merely finite norm. The differential graph domain of this strong-source degree-one space is $\kappa_0^{-1}\mathbb{C}[s]$, by the same highest-pole calculation as TA4 at every p .

Thus the strong-source complex is the explicit subcomplex

$$[\kappa_0^{-1}\mathbb{C}[s] \xrightarrow{D_{\text{exp}}} \kappa^{-1}\mathbb{C}[s] ds]. \tag{TA11}$$

It injects into the Hilbert-admitted and full analytic cohomologies with no extra kernel, by the same D_{exp} -preimage proof. Its residue image is exactly $\mathbb{C}^{S_B}$. In particular a ν -root off the critical line with $m_p = 0$ is admitted by the Hilbert norm but not by B ; its exact omitted coordinate is its AP residue.

241.5 5. Polynomial coordinates, source maps and every retained boundary defect

Use the literal maps $Q \mapsto Q/\kappa_0$ in degree zero and $P \mapsto P/\kappa$ in degree one. They carry TA11 to a polynomial complex with differential

$$\begin{aligned} E(Q) &= \kappa D_{\exp}(Q/\kappa_0) \\ &= ubQ' + [b(h-t) - uc]Q. \end{aligned} \quad (\text{TA12})$$

The quotient $\kappa'_0/\kappa_0 = \sum_p (m_p - 1)/(s - p)$ proves this identity with all orders and the negative derivative term retained. Since b and h are the specified monic polynomials, the leading term of $E(Q)$ has degree $\deg Q + d + |S_B|$ and unchanged leading coefficient. Every other term has lower degree. Thus E is injective and its cokernel has the unique polynomial basis of degrees less than $d + |S_B|$, by terminating leading-term reduction.

The original polynomial exponential complex maps into it by the exact square

$$\begin{array}{ccc} \mathbb{C}[s] & \xrightarrow{D_{\exp}} & \mathbb{C}[s] \\ \text{multiplication } \kappa_0 \downarrow & & \downarrow \text{multiplication } \kappa \\ \mathbb{C}[s] & \xrightarrow{E} & \mathbb{C}[s] \end{array} \quad (\text{TA13})$$

$$E(\kappa_0 Q) = \kappa D_{\exp} Q.$$

Leibniz differentiation proves this directly, or use the denominator maps. The original arithmetic source is carried identically, since $V_{h,\text{rat}}((\kappa P)/\kappa) = P(D_x)F_h$. No map here sends supported zero to τ or changes the base point; lift each displayed linear map on its original mask.

There is also an exact arithmetic-quotient map, with its boundary value fully retained. Write $E_H = \mathbb{C}[s]/(H)$, $v_H = j_H(g/H)$, and use the existing full packet section $\sigma_H : E_H \rightarrow Q = B/\Theta V$. For the original full jet J_H ,

$$\begin{aligned} J_H V_{h,\text{rat}}(P/\kappa) &= v_H[P]_H, \\ qV_{h,\text{rat}}(P/\kappa) &= \sigma_H(v_H[P]_H). \end{aligned} \quad (\text{TA14})$$

To justify the second equation, $H(D_x)P(D_x)F_H = \Theta(P(D_x)\phi_*)$ by Mellin identity and injectivity, so its Q -class lies in $Q[H(D_x)]$. On that actual submodule the original full-jet map and σ_H are inverse. Thus the displayed equation follows from the first one, which is the literal product of Taylor series. Restriction to the original h -block gives

$$j_h(\kappa v_H P) = v_h[P]_h. \quad (\text{TA15})$$

At each added κ -block, κP vanishes through its full order. The old source inclusion therefore retains its actual full-unit h -component and has zero added components, not a hidden mixture of old and new source classes.

For a geometric degree-zero numerator Q the observed boundary is exactly

$$qV_{h,\text{rat}}(E(Q)/\kappa) = \sigma_H(v_H[E(Q)]_H). \quad (\text{TA16})$$

It need not be zero. TA16 is the calculated defect preventing an unproved descent from geometric de Rham cohomology to the original theta quotient. The cochain source map, its full-unit jet value and its entire residual boundary have all been supplied; no false cohomology intertwiner replaces them.

At the fixed-domain specialization $u = t = 0$, $E = bh$. The quotient of the original arithmetic E_H by its ideal $(bh)/(H)$, transported by the unit v_H , is exactly the geometric polynomial quotient $\mathbb{C}[s]/(bh)$. At an added root p this ideal is $(s - p)/(s - p)^{m_p}$; at an original h -root its component is zero. This computes the complete endpoint kernel, including every removed higher jet, instead of identifying the two quotients outright. For $m_p = 1$ that component is zero. Its rank count is $d + |S_B|$, with no deletion from the larger original E_H before the specified quotient map.

The fixed pair TA11 was derived for $u \neq 0$. At $u = 0$, recomputing the maximal graph domain allows all coefficients in $\kappa^{-1}\mathbb{C}[s]$, since $h - t$ has no pole; that is a different degree-zero domain.

At $u = t = 0$ its localized cohomology has rank d . The fixed-domain specialization just calculated has rank $d + |S_B|$. Both domains and the exact endpoint quotient are explicit; no flatness of the recomputed graph domain is asserted.

241.6 6. The actual theta Gram and finite source cost

For the literal denominator frame TA10, TA2 becomes the exact identity

$$\begin{aligned} \|V_{h,\text{rat}}(P/\kappa)\|^2 &= \int_{\mathbb{R}} |P(1/2 + iy)|^2 w_H(y) dy, \\ w_H(y) &= |(g/H)(1/2 + iy)|^2 / (2\pi), \quad \int w_H = \mu_H. \end{aligned} \quad (\text{TA17})$$

All removable values on the line are filled by the original entire g/H . This is the already specified arithmetic convolution seed for the actual extended packet H , with its own full mass μ_H , not a unit-mass replacement. For any finite numerator degree N , the exact Gram is

$$(M_{H,N})_{ij} = \int_{\mathbb{R}} \overline{(1/2 + iy)^i} (1/2 + iy)^j w_H(y) dy, \quad 0 \leq i, j \leq N. \quad (\text{TA18})$$

It is positive definite: a nonzero polynomial is nonzero outside a finite set, and the nonzero entire g/H is nonzero almost everywhere on the line. All moments converge by the original rapid vertical decay. In an arbitrary specified finite rational basis R_j , the unchanged norm instead has matrix $\int \overline{R_i} R_j w_h$; TA17–18 are its exact denominator-coordinate pullback, not a change of norm.

Let E_N be the coefficient matrix of TA12 from degrees $\leq N$ to degrees $\leq N + d + |S_B|$. The full source cost of the actual geometric boundary is

$$\|V_{h,\text{rat}}(E(Q)/\kappa)\|^2 = Q^* E_N^* M_{H,N+d+|S_B|} E_N Q. \quad (\text{TA19})$$

This includes u, t , every m_p through c , and all cross terms. Its arithmetic class is TA16. If G_H is an existing canonical quotient Gram at an admitted cutoff and T_N is the literal matrix $Q \mapsto v_H[E(Q)]_H$, the quotient cost is exactly $Q^* T_N^* G_H T_N Q$. No new quotient metric is selected. No uniform bound on these actual matrices is inferred from their positivity.

Completed result: all analytic pole classes have their exact original-Hilbert admission test; those with genuine strong-Schwartz source representatives are realized by an actual enlarged full-zero packet. Their complex, residues, source Gram and arithmetic boundary defect are explicitly calculated.

241.7 7. The connection in the same arithmetic numerator frame

Write $r = |S_B|$ and $q = d + r$. In the degree-one numerator frame $f_j = s^j/\kappa$, $0 \leq j < q$, the actual connection is

$$\begin{aligned} L &= u \frac{d}{dt} - A_{\text{adm}}(u, t), \\ A_{\text{adm}} &= \text{Companion}(\chi_{\text{adm}}), \\ \chi_{\text{adm}}(u, t; s) &= b(s)(h(s) - t) - uc(s). \end{aligned} \quad (\text{TA20})$$

Here Companion means the column-convention matrix taking e_j to e_{j+1} for $j < q - 1$ and taking e_{q-1} to minus the coefficient column of the lower-degree part of the displayed monic polynomial. This specifies every matrix entry without a basis convention left implicit.

Indeed $[L, E] = 0$ on parameter-dependent polynomial numerators: the term $[u d/dt, E] = -ub$ cancels $[-s, ub d/ds] = ub$, and all remaining commutators vanish. Thus L descends through the

parameter-dependent cokernel. Its value on f_j is $-s^{j+1}/\kappa$. Only the last basis vector requires reduction, and the exact reduction relation is $E(1) = \chi_{\text{adm}}$. This proves TA20. It does not assert that multiplication by s alone descends on the fixed quotient by the image of the differential operator E . Nor is χ_{adm} being declared an annihilator made of new actual zeros of g . It is the calculated connection matrix in the already admitted arithmetic frame.

Here is its exact relation to AP's polynomial-plus-simple-pole frame. Use that frame restricted to S_B , and denote its connection matrix by $T_B = \begin{bmatrix} A(t) & B_{S_B} \\ 0 & \text{diag}(p) \end{bmatrix}$. Let $G(u, t)$ be the matrix whose j th column is the AP coordinates of $[s^j/\kappa]$. Its residue-block entries are

$$\begin{aligned} G_{(p,j)} &= \text{Res}_p(w(s)s^j/\kappa(s) ds)/w(p) \\ &= \frac{\left(\frac{d}{ds}\right)^{m_p-1} [w(s)s^j/\kappa_p(s)] \Big|_{s=p}}{(m_p-1)!w(p)}, \\ \kappa_p(s) &= \kappa(s)/(s-p)^{m_p}. \end{aligned} \tag{TA21}$$

All m_p derivatives, the original exponential weight, and its value $w(p)$ are retained. To compute the polynomial-block entries, subtract the simple poles with these coefficients from f_j . The result has zero weighted residue at every admitted point. Take AP's log-free local primitives, keep their finite principal parts, and subtract their D_{exp} images. This leaves a polynomial. Reduce it to degree less than d with the original leading-term reduction for D_{exp} . These coefficients are exactly the remaining entries of G . This is a finite formula for each column, not a choice of an unspecified comparison map.

Both sets are proved bases of the same admitted cohomology, so G is invertible. The primitive calculations only divide by nonzero $u, w(p)$, nonzero leading coefficients, and fixed nonzero differences of distinct points. Their finite coefficients are therefore holomorphic for $u \neq 0$ and all t . Applying L to each column, with its parameter dependence included, gives the exact identity and finite scaling transport

$$\begin{aligned} uG_t &= T_B G - G A_{\text{adm}}, \\ A_{\text{adm}} &= G^{-1} T_B G - uG^{-1} G_t, \\ C_{\text{adm}}(a; t) &= G(t)^{-1} C_B(a; t) G(t + ua). \end{aligned} \tag{TA22}$$

The fixed u is suppressed only in the last line's arguments. For proof of that line, differentiate its right side with respect to a , use $C'_B(a; t) = -C_B(a; t)T_B(t + ua)$, and then the first identity of TA22. The derivative is $-C_{\text{adm}}(a; t)A_{\text{adm}}(t + ua)$ and the value at $a = 0$ is I . The uniqueness of this finite linear differential equation proves the transport formula. Both endpoint frames and the derivative gauge term are present; a pointwise similarity would omit an actual term.

These same numerator vectors are the actual source vectors $D_x^j F_H$ by TA10, so their original norm is the explicitly calculated $M_{H,q-1}$. The cohomological frame change G , however, also used D_{exp} primitives. Those primitive differences have exactly the source cost TA19 and the full arithmetic image TA16. A norm isometry between arbitrary reduced representatives is not silently inferred from a cohomology change of basis. Thus TA20–22 supply the concrete arithmetic-frame connection, its exact comparison with AP, and the already computed source-level discrepancy.

241.8 8. Exact recovery of the old canonical quotient metric

The comparison reaches the original quotient metric as well as individual source vectors. Put $K = \deg \kappa$ and $D = \deg H = d + K$. Use the literal injection

$$i_\kappa : \mathbb{C}[s]/h \longrightarrow \mathbb{C}[s]/H, \quad [P]_h \longmapsto [\kappa P]_H.$$

It is well-defined because $H = h\kappa$ and injective because the polynomial ring has no zero divisors. Its image is the ideal $(\kappa)/(H)$. At the old h -block it multiplies by the actual nonzero Taylor unit $j_h(\kappa)$; at every new block it is zero through that block's full order. Composing with v_H yields precisely the original arithmetic unit v_h by TA15, not a newly chosen identification of the h -component.

Let $R_{H,N}^{\text{coef}}$ be the existing unique least-source-norm representative for coefficient classes in $\mathbb{C}[s]/H$ among polynomials of degree at most N ; let $G_{H,N}^{\text{coef}}$ be its Gram. Define $R_{h,N-K}^{\text{coef}}$ and $G_{h,N-K}^{\text{coef}}$ in precisely the same way using the original weight w_h . Take $N \geq D - 1$ so both quotient maps are onto and both metrics are defined. Then, as maps and forms,

$$\begin{aligned} R_{H,N}^{\text{coef}} i_\kappa &= M_\kappa R_{h,N-K}^{\text{coef}}, \\ i_\kappa^* G_{H,N}^{\text{coef}} i_\kappa &= G_{h,N-K}^{\text{coef}}. \end{aligned} \tag{TA23}$$

where M_κ is literal polynomial multiplication. These are the original least-norm constructions, not newly selected quotient metrics.

For proof, a degree-at-most- N representative Q of $i_\kappa[P]_h$ has $Q - \kappa P = HT$ for some polynomial T . Thus $Q = \kappa R$ with $[R]_h = [P]_h$ and $\deg R \leq N - K$. Conversely every such R gives an allowed Q . This is a bijection between the two complete affine spaces of representatives, including all their relation directions. Their norms agree exactly:

$$\begin{aligned} \int |\kappa(s)R(s)|^2 w_H(y) dy &= \int |R(s)|^2 w_h(y) dy, \quad s = 1/2 + iy, \\ w_h(y) &= |\kappa(1/2 + iy)|^2 w_H(y). \end{aligned} \tag{TA24}$$

The last identity is $g/h = \kappa g/H$, with the removable line values filled by those entire functions. It retains both unnormalized masses; neither mass is asserted equal to the other. Finite-dimensional positive definiteness gives a unique minimizer in each affine space. The norm bijection therefore proves the first identity of TA23, and polarization proves its full Hermitian Gram identity, including cross terms.

Under the actual source maps the two minimizing polynomials give the identical strong-Schwartz function:

$$(R_{H,N}^{\text{coef}} i_\kappa [P])(D_x)F_H = (R_{h,N-K}^{\text{coef}} [P])(D_x)F_h,$$

because $\kappa(D_x)F_H = F_h$ follows from the original Mellin transforms. Thus TA23 is a calculated isometric inclusion of the original arithmetic quotient observation into the extended-packet observation with the exact degree shift K . It is stronger than a bound inferred from positivity. For precision about full-unit coordinates, write $G_{H,N}^{\text{jet}}$ for the same canonical observation expressed in physical jet coordinates $J_H = v_H \pi_H$. Then

$$\begin{aligned} G_{H,N}^{\text{coef}} &= M_{v_H}^* G_{H,N}^{\text{jet}} M_{v_H}, \\ j &= M_{v_H} i_\kappa M_{v_h}^{-1}, \\ j^* G_{H,N}^{\text{jet}} j &= G_{h,N-K}^{\text{jet}}. \end{aligned}$$

Here M_v denotes multiplication by the indicated complete Taylor unit, not its leading coefficient. TA15 proves that j is exactly the identity on the original h -block and zero on each added full κ -block. These equations specify the equivalent metric statement in the physical jet convention used for the arithmetic cost in TA19. No unit-coordinate change is left implicit or omitted from a Gram pullback.

TA23 does not identify the extra quotient directions or their mixed Gram entries with old directions. Those remain in the actual extended metric; the geometric-boundary image TA16 and its source cost TA19 remain unchanged.

241.9 Sources and verification scope

Root reread A1–A5 of the current `tex/arithmetic_input.tex`, including the definition of B , $g = 2\xi$, $\Theta\phi_*$, and the original Euler inverse. The full A1–A19 source and its full-order section were read previously. AP1–26 is the accepted analytic input, SHA256 357923aead35c77f2fa98598fbc4ed8bc1f7cd6ebc04760da504a0ded765a652. The independent collaborator derived and checked TA3–TA7, the global graph domain and TA12–TA16 while root wrote their complete proofs and source-cost formulas here. This note claims written mathematics, not new Lean execution, numerical zero certification, a uniform estimate, or remote publication.

Independent calculation and review of theta-admitted pole complexes

Date: 2026-09-13. This records the independent calculation supplied while the root proof THETA_ADMITTED_POLE_COMPLEX.md was being written. A final review seal, if appended below, identifies the complete root version read and accepted. No source-owner or publication file is edited here. There is no numerical, arithmetic-zero, Lean, or quotient-positivity certificate.

1. Exact admission for the stipulated critical-line norm

Keep the original entire function $v_h = g/h$, with h containing the full selected zero orders. Its norm on a rational coefficient F is exactly

$$\int_{\mathbb{R}} \left| v_h \left(\frac{1}{2} + iy \right) F \left(\frac{1}{2} + iy \right) \right|^2 \frac{dy}{2\pi}.$$

The parameter y on this line is distinct from the deformation parameter t in $D = u\partial_s + h - t$. Throughout the pole-complex calculation u is fixed and nonzero. No phase, cancellation, or mass in this integral is replaced by a discrete or diagonal surrogate.

Let P be the distinct roots of the actual Hermite polynomial ν , and let O and C be its off-line and critical-line subsets. At $p \in C$ put $m_p = \text{ord}_p(v_h)$. If F has an actual pole of order n at p , the weighted integrand is a nonzero smooth factor times $|y - y_p|^{2(m_p - n)}$ locally. Its integrability is equivalent to $2(m_p - n) > -1$, hence exactly to $n \leq m_p$, since both orders are integers. Apparent terms whose leading coefficients cancel must first be combined into F 's actual Laurent order.

There is no obstruction at infinity for a rational F . This can be checked from the original source without a new zeta estimate: A1–A3 give $g = \text{Mellin}(\Theta\phi_*)$ with $\Theta\phi_*$ in the strong-Schwartz space. Its Mellin restriction to any fixed vertical line is a Schwartz Fourier transform after $x = \exp(r)$. Division by h preserves this rapid decay at infinity, and the selected finite singularities are removable. Rational functions and their derivatives grow at most polynomially away from their finite poles. Off-line poles therefore impose no further condition for this line norm. Indeed every admitted weighted restriction $v_h F$ is Schwartz on the line, not merely square-integrable.

This statement proves exactly line-norm admission. It does not turn a meromorphic off-line Mellin multiplier into an entire Mellin transform.

2. The maximal two-term norm-admitted complex

Write PP_p for finite principal parts at p , and $\text{PP}_p^{\leq j} = 0$ for $j \leq 0$. The degree-one admitted rational space and its degree-zero graph domain are

$$A^1 = \mathbb{C}[s] + \bigoplus_{p \in O} \text{PP}_p + \bigoplus_{p \in C} \text{PP}_p^{\leq m_p},$$

$$A^0 = \mathbb{C}[s] + \bigoplus_{p \in O} \text{PP}_p + \bigoplus_{p \in C} \text{PP}_p^{\leq \max(m_p - 1, 0)}.$$

All sums here are direct as polynomial-plus-principal-part vector spaces. The complex is $[A^0 \xrightarrow{D} A^1 ds]$. It is the maximal such subcomplex of the analytic localization with the stipulated degree-one admission:

$$A^0 = D^{-1}(A^1) \text{ inside } \mathbb{C}[s, \nu^{-1}].$$

Indeed, at a pole of order $n \geq 1$ in Q , the highest pole of DQ has order $n + 1$ and coefficient $-un$ times the leading coefficient of Q . The multiplier $h - t$ cannot cancel it. Consequently DQ is admitted at a critical point exactly when Q has no pole or has order at most $m_p - 1$. Such a Q is automatically

in A^1 as well. This proves the asserted maximal graph domain rather than assuming D preserves the original degree-one space.

Let $S = O \cup \{p \in C : m_p \geq 1\}$ and $Z = \{p \in C : m_p = 0\}$. The weighted analytic residue of AP, with $w = \exp((\Phi - ts)/u)$, has exactly the image $\mathbb{C}^S$ on the admitted complex. Its coordinates on Z vanish identically. For every $p \in S$, the admitted lift $1/(w(p)(s - p))$ gives the p -th coordinate vector, with its actual weight retained.

If an admitted degree-one F has zero weighted residues, the AP local primitive construction gives a rational Q with $DQ - F$ polynomial. At a critical point, Q has pole order at most one less than F , so Q belongs to A^0 ; at every off-line point no additional restriction is imposed. Thus the same proof gives the exact sequence

$$0 \longrightarrow H_{\text{pol}} \longrightarrow H^1(A) \longrightarrow \mathbb{C}^S \longrightarrow 0.$$

A basis is $1, s, \dots, s^{d-1}$ followed by $1/(s - p)$ for $p \in S$. In particular $\dim H^1(A) = d + |S|$ and $H^0(A) = 0$. Full multiplicities m_p remain in the cochain spaces and their differentials; the single residue coordinate per admitted point is a proved cohomological quotient.

3. Exact map to AP and absence of an additional kernel

If an admitted F is DQ in the full analytic localization, the graph-domain identity forces Q into A^0 . Therefore the induced cohomology map is injective: restricting degree zero in this maximal way creates no extra kernel. Its image is exactly the classes whose weighted residues on Z vanish. In full, the actual map fits into

$$0 \longrightarrow H^1(A) \longrightarrow H_{\text{loc}} \longrightarrow \mathbb{C}^Z \longrightarrow 0,$$

where the last map is the corresponding coordinate restriction of AP's weighted-residue map. This also accounts for all cokernel coordinates.

There is a direct quotient-complex check. At critical p with $m_p \geq 1$, the quotient complex is

$$\text{PP}_p / \text{PP}_p^{\leq m_p - 1} \xrightarrow{D} \text{PP}_p / \text{PP}_p^{\leq m_p}.$$

Its differential is bijective: remove the highest target pole with the unique predecessor having one lower order, and continue downward; all remaining target orders at most m_p are zero in this quotient. Injectivity is the same leading-pole argument. At $m_p = 0$ the quotient is the full AP principal-part complex with its one-dimensional residue cokernel. At off-line points the quotient is zero. Hence this computation gives exactly the preceding short exact sequence and no hidden additional classes.

The operator $L = u\partial_t - s$ preserves both A^0 and A^1 and commutes with D . Multiplication by s does not raise any finite pole order, and t differentiation does not alter these fixed pole bounds. The admitted connection, weighted-residue transition, and scaling matrix are therefore AP's matrices with precisely the pole rows and columns in S retained: $\begin{bmatrix} A(t) & B_S \\ 0 & P_S \end{bmatrix}$, W_S , and their displayed off-diagonal integral. This is an invariant subfamily, not a chosen replacement operator.

4. Entire-Mellin admission and the actual strong-Schwartz source

For this stronger admission put $m_p = \text{ord}_p(v_h)$ at every p in P , not just on the critical line. Since $\gcd(h, \nu) = 1$, h does not vanish at these points and this equals $\text{ord}_p(g)$. Let

$$\begin{aligned}
k &= \prod_{m_p > 0} (s - p)^{m_p}, \\
k_0 &= \prod_{m_p > 0} (s - p)^{m_p - 1}, \\
b = k/k_0 &= \prod_{m_p > 0} (s - p).
\end{aligned}$$

The empty products are one. The rational coefficients F for which $v_h F$ is entire are exactly $k^{-1}\mathbb{C}[s]$. Their graph domain under D for u nonzero is $k_0^{-1}\mathbb{C}[s]$, by the same leading-pole argument. The inclusion into the line-norm admitted complex is literal. Its image on cohomology retains just the residues at points with $m_p > 0$, and it is injective by the same maximal-domain argument. Thus the difference from the line-norm domain consists exactly of off-line points where $m_p = 0$.

This stronger space has an exact realization in the original source, not only a formal entire-function criterion. Set $H = hk$. Every root of H is an actual g -zero with its full order, and its two factors have disjoint root sets. The original repeated-root division construction gives $F_H = S_H \Theta \phi_*$ in the strong-Schwartz space, with Mellin transform g/H . Consequently

$$V(P/k) = P(D_x)F_H, \text{ where } D_x = -x\partial_x,$$

has Mellin transform $gP/H = v_h P/k$. This proves sufficiency by the original source construction. Necessity follows because the Mellin transform of a strong-Schwartz source is entire: every pole of $v_h F$ must cancel. The coefficient derivative ∂_s in D is not D_x ; the latter corresponds to multiplication by s under Mellin transform.

The full source jet map is

$$J_H V(P/k) = v_H[P]_H,$$

with the actual complete unit $v_H = j_H(g/H)$. On the old polynomial inclusion the target numerator is kP ; restricting to the original h packet gives $j_h(kv_H P) = v_h[P]$. At newly added roots kP vanishes to the full corresponding orders. These identities retain all original jets and the full Taylor units; they do not replace them by leading values.

5. Polynomial coordinates for the stronger complex

Under the degree-zero and degree-one denominator identifications, put

$$c = bk'_0/k_0 = \sum_{m_p > 0} (m_p - 1)b/(s - p).$$

This is a polynomial, including when some or all m_p equal one. The exact polynomial differential is

$$E = ub\partial_s + b(h - t) - uc,$$

because $kD(P/k_0) = E(P)$. The old polynomial complex embeds by multiplication by k_0 in degree zero and k in degree one:

$$E(k_0 P) = kD(P).$$

If $q = d + \deg b$, the leading term of $E(P)$ for nonzero polynomial P has degree $\deg P + q$ and unchanged leading coefficient. The derivative and c terms have strictly smaller degree. Hence E is injective, its cohomology is free on the degree-below- q remainder basis at fixed parameters, and its dimension q agrees with the exact residue sequence.

The commuting connection in this numerator basis is also explicit. $[u\partial_t - s, E] = 0$, and the last basis column is reduced using $E(1) = b(h - t) - uc$. Thus its matrix is

$$u\partial_t - \text{Companion}(b(h - t) - uc).$$

It need not be pointwise similar to AP's polynomial-plus-simple-poles block: their parameter-dependent frame transition is a connection gauge, whose derivative term must be included. In particular c records the full multiplicities without changing the original arithmetic packet H .

These coefficient/source maps are degreewise. An exponential boundary $E(P)$ need not be an arithmetic theta boundary; its exact arithmetic jet observation is $\nu_H[E(P)]_H$. No descent through the arithmetic quotient is asserted by merely writing a strong-Schwartz representative. Likewise the fixed pair with denominators k_0, k is the maximal graph domain only when u is nonzero. Setting $u = 0$ in its matrix is not the same as recomputing the maximal graph domain, which then admits the full orders m_p in degree zero as well.

Source and verification scope

The original source identities A1–A3 were reread in `arithmetic_input.tex`. Its previously recorded SHA-256 is `a50b0fb587b644c4ea94dba45b2b423d038f2bfbef7fef188543939ba850e58d2`. The repeated-root primitive, full-unit section, and exact original source were read completely in the prior independent scaling work. The accepted AP proof supplies the already independently checked local weighted-residue primitive and entire transport, with no change of arithmetic input.

All cohomology assertions above are algebraic. Finite norm of the displayed representatives does not by itself prove closedness of the boundary range or a nondegenerate induced quotient norm. This review neither chooses a new metric nor asserts such a conclusion.

Full read of the root TA1–19 proof

The complete root TA1–19 note was read after it became available, including its source, endpoint, and cost paragraphs. No mathematical correction was required in that version. In addition to the independent calculations above, the following root extensions were checked directly.

First, the original source identification descends exactly to its stated arithmetic-quotient value. Multiplying $P(D_x)F_H$ by $H(D_x)$ gives $\Theta(P(D_x)\phi_*)$, so its Q -class belongs to the actual H -torsion submodule. The original packet section is inverse to the full jet map there. This proves the root's $qV(P/\kappa) = \sigma_H(\nu_H[P]_H)$ with the complete unit. Applying the same identity to $E(Q)$ proves the exact nonzero boundary observation; no assertion of geometric-boundary descent is needed or made.

Second, at the fixed-pair endpoint $u = t = 0$ the geometric polynomial differential is multiplication by bh . Since bh divides H , the map $\mathbb{C}[s]/H \rightarrow \mathbb{C}[s]/(bh)$ is onto with kernel $(bh)/(H)$. At an old h -root its kernel is zero, and at an added p it is exactly $(s - p)/(s - p)^{m_p}$. The kernel dimension is $\sum_{p \in S_B} (m_p - 1)$, and the quotient dimension is $d + |S_B|$. Multiplication by the actual unit preserves this ideal and gives the stated transported comparison. Recomputing the graph domain at $u = t = 0$ instead uses κ in both degrees and produces the rank- d quotient. This verifies both endpoint statements with their distinct domains.

Third, TA17–19 are exact pullbacks of the retained source norm. For numerator P the weight is $|g/H|^2/(2\pi)$, with the original unrenormalized mass. Its Gram is positive on every finite polynomial coefficient space because g/H is a nonzero entire function and a nonzero polynomial has only finitely many zeros. All moments converge by the original source's rapid vertical decay. For a fixed matrix E_N , expanding the original quadratic form gives precisely $Q^*E_N^*M_HE_NQ$, including every cross term. Composing instead with the existing arithmetic quotient map and its specified G_H gives $Q^*T_N^*G_HT_NQ$. These equalities are changes of coordinates in given forms; they do not define a new quotient norm or infer a uniform estimate from positive definiteness.

Complete review of TA20–22 and the frame transport

The full new Section 7 was read, including the explicitly stated column companion convention, the finite primitive construction of G , its holomorphic parameter domain, and the source-discrepancy paragraph. Its formulas agree exactly with the independent connection calculation.

For each numerator vector s^j/κ , the simple-pole AP coefficient at p is its weighted residue divided by $w(p)$. Expanding κ at its full order m_p gives exactly TA21's derivative of order $m_p - 1$ and factorial $(m_p - 1)!$. The complementary factor κ_p is nonzero at p . After subtracting those simple poles, AP's primitive reduces the remaining zero-residue rational coefficient within the admitted degree-zero bound. Polynomial leading-term reduction then supplies its unique old-polynomial coordinates. This proves that the displayed finite algorithm computes G with every required unit, derivative, and residue value retained.

The two bases have already been proved independent and spanning, hence G is invertible without a separate determinant assumption. The finite algorithm has only the stated nonzero denominators on u nonzero and all t ; a value $h(p) - t = 0$ does not introduce an unlisted division. Thus the asserted holomorphic parameter domain is correct, including the empty-pole case in which G is the identity.

The frame orientation is AP coordinates = G times numerator coordinates. Applying L gives $uG_t - T_B G = -GA_{\text{adm}}$, which is TA22 with exactly the negative derivative term in $G^{-1}T_B G - uG^{-1}G_t$. Differentiating $G(t)^{-1}C_B(a; t)G(t + ua)$ therefore yields $-C_{\text{adm}}(a; t)A_{\text{adm}}(u, t + ua)$, with initial value identity. This checks the matrix order, signs, source and target parameter fibres, and both endpoint frame factors. No pointwise similarity is substituted for the connection gauge.

The representative differences used to construct this cohomological frame change are actual D_{exp} primitives in the strong-source graph domain. Their source images consequently have precisely the already computed TA19 cost and TA16 arithmetic boundary value. Keeping this discrepancy prevents an unjustified source-norm isometry or arithmetic cohomology descent from being inferred from G .

Final independent acceptance

The complete root proof TA1–22, including all unnumbered scope statements and the final source paragraph, has now been read and checked. The exact accepted artifact is THETA_ADMITTED_POLE_COMPLEX.md, SHA-256:

3f9a79e61de1f38bc0944be4e43b1ef20f02f99b55637f3afa8b773fb38cf8ec.

Final disposition: accept TA1–22 with no outstanding mathematical correction. This is a written-proof review of the norm and strong-source admission, both maximal graph complexes, exact residue images and injections, full-packet source realization, retained arithmetic boundary defect, endpoint quotient, actual Gram/cost pullbacks, and connection frame transport. No numerical fixture, arithmetic-zero evaluation, Lean replay, uniform metric bound, or new Frobenius identification is certified by this acceptance.

Additive review of the exact canonical-metric recovery, TA23–24

The complete Section 8 was subsequently read, including its explicit coefficient-versus-physical-jet conventions. The preceding TA1–22 seal and its hash remain a historical acceptance of that earlier version. The following checks concern the additive TA23–24 continuation.

Set $K = \deg \kappa$, so K includes every full added zero order, not merely the number of distinct added points. With $D = \deg H = d + K$, the stated cutoff $N \geq D - 1$ gives $N - K \geq d - 1$. Both coefficient quotient observations are therefore onto, including the endpoint cutoffs and the empty-added- packet case $K = 0$. Multiplication by κ is injective from $\mathbb{C}[s]/h$ to $\mathbb{C}[s]/H$ because $H = h\kappa$ in the polynomial integral domain.

Fix a coefficient class $[P]_h$. A representative Q of its image satisfies $Q - \kappa P = HT$ if and only if $Q = \kappa R$ with $[R]_h = [P]_h$. Because multiplication by the nonzero degree- K polynomial κ shifts the degree of every nonzero R by exactly K , the restriction $\deg Q \leq N$ is exactly $\deg R \leq N - K$. Zero is included separately with no difficulty. This proves a bijection of the whole affine representative spaces, not only an injection of selected representatives or a comparison inequality.

The pointwise identity $v_H \kappa = v_h$ gives equality of the original norms for each pair of corresponding representatives, with their original measure and neither source mass renormalized. Positive definiteness of the finite coefficient Grams gives unique minimizers; the bijection therefore proves the representative identity in TA23. Polarization proves its full Hermitian-form identity, retaining all mixed terms among old quotient directions. The actual source vectors coincide because $\kappa(D_x)F_H = F_h$ by Mellin injectivity. Thus there is no unrecorded source representative or cutoff defect.

The addendum correctly distinguishes G^{coef} from the physical-jet G^{jet} used in TA19. For $U_H = M_{v_H}$ and $U_h = M_{v_h}$, the identities

$$\begin{aligned} G_H^{\text{coef}} &= U_H^* G_H^{\text{jet}} U_H, \\ j &= U_H i_\kappa U_h^{-1} \end{aligned}$$

give $j^* G_H^{\text{jet}} j = G_h^{\text{jet}}$ at the stated respective cutoffs. On the original h -block, $v_H \kappa = v_h$ proves that j is identity. On every added block it is zero through the full order because κ vanishes to that order and both units are genuine full Taylor units. This is precisely the original packet's extension by zero in physical jets, not the bare coefficient multiplication map silently reused in a different coordinate convention.

No orthogonality to the added directions follows or is claimed. Their mutual and mixed Gram entries remain in the extended metric. TA16's arithmetic boundary value and TA19's full cost are unchanged. Therefore the addendum establishes an exact restriction of the existing canonical metrics, without selecting a new metric or deriving a uniform estimate.

Final acceptance of TA1–24

The complete added Section 8 and its final unit-coordinate clarification have been read and checked. The exact accepted proof is `THETA_ADMITTED_POLE_COMPLEX.md`, SHA-256:

830e9a254465434fd61cb16212544f004ddf54a5adc72554bccabe217b045e5a.

Final disposition: accept TA1–24 and their stated scope, with no outstanding mathematical correction. This supersedes only the version pin of the earlier TA1–22 acceptance, which remains recorded above. The present addition is a written-proof review of exact cutoff, minimizer, source-map, and full-unit Gram identities; it includes no numerical replay, Lean execution, arithmetic-zero evaluation, or uniform metric-bound claim.

242 Counterfactual RH search on the original split-supported theta input

242.1 Scope

The preceding Deligne-bound audit is not a no-go theorem for geometry over F_1 , for the monoidal base τ , or for a future purity construction using the full arithmetic input. Its stated conclusion concerns a particular inference from an auxiliary exponential family's Frobenius purity to a bound for the original theta metric. Its examples do not assert that their chosen polynomials divide the original function $g = 2\xi$.

This continuation takes the counterexample search as an independent research objective. It proves a finite-sign certificate for a counterexample to RH, directly from derivatives of the original theta function. It also proves that an actual counterexample would eventually supply such a certificate. The finite calculation reported below found no negative witness. No counterexample to RH is claimed.

The power-sum/moment method belongs to established zero-positivity methods; see Zhang (2015). The derivation below gives all its maps, signs, and constants for the present source, rather than claiming a new general RH criterion.

242.2 1. Original input and support

Retain

$$G(R) = \{\tau\} \sqcup R^\bullet, \quad e_R = 0_R^\bullet, \quad p_R(\tau) = 0, \quad p_R(r^\bullet) = r,$$

and the coefficient square

$$\begin{array}{ccc} G(\mathbb{Z}) & \longrightarrow & G(\mathbb{C}) \\ p_{\mathbb{Z}} \downarrow & & \downarrow p_{\mathbb{C}} \\ \mathbb{Z} & \longrightarrow & \mathbb{C}. \end{array}$$

The support observation sends τ to Boolean zero and every represented coefficient to Boolean one. On the original support-labelled coefficient fibres, a linear map lifts as $(\ell, v) \mapsto (\ell, fv)$, with external absence fixed. A killed coefficient therefore reaches $(\ell, 0)$, not external absence. No conclusion about the sign of an arithmetic functional follows just from that support value.

Use the unchanged source

$$\Theta\phi(x) = 2 \sum_{n \geq 1} \phi(nx), \quad \phi_*(x) = (4\pi^2 x^4 - 6\pi x^2) e^{-\pi x^2},$$

$$f_0 = \Theta\phi_*, \quad \mathcal{M}f_0(s) = g(s) = 2\xi(s) = s(s-1)\pi^{-s/2}\Gamma(s/2)\zeta(s).$$

These are the arithmetic-input equations (A1)–(A3), also identified with the specified Hochschild trace in HOCHSCHILD_COMPARISON.md, equations (H4)–(H10). Define the explicit logarithmic-coordinate function

$$\psi(y) = e^{y/2} f_0(e^y). \tag{1}$$

Mellin substitution gives

$$g(1/2 + iz) = \int_{\mathbb{R}} \psi(y) e^{izy} dy. \tag{2}$$

The original reflection $f_0(x) = x^{-1}f_0(1/x)$ gives $\psi(-y) = \psi(y)$. This reflection also follows by applying the source Fourier identity to ϕ_* : Fourier sends D to $1 - D$, so it fixes $(D^2 - D)e^{-\pi x^2} = \phi_*$.

For $x \geq 1$, every summand in $f_0(x)$ is positive, since

$$4\pi^2 n^4 x^4 - 6\pi n^2 x^2 = 2\pi n^2 x^2 (2\pi n^2 x^2 - 3) > 0.$$

Reflection proves positivity for all $x > 0$. The Gaussian series also gives a constant C such that

$$0 < \psi(y) \leq C \exp(9|y|/2 - \pi e^{2|y|}). \quad (3)$$

For $y \geq 0$, bound the convergent sum of $n^4 e^{-\pi(n^2-1)e^{2y}}$ by its value at $y = 0$; reflection supplies the other half-line. Thus all differentiations and all moments below converge absolutely.

242.3 2. Coefficients with the original mass retained

Put

$$M_{2j} = \int_{\mathbb{R}} y^{2j} \psi(y) dy = g^{(2j)}(1/2), \quad a_j = \frac{(-1)^j M_{2j}}{(2j)!}. \quad (4)$$

Define the entire function F by its specified coefficients:

$$F(w) = \sum_{j \geq 0} a_j w^j, \quad F(z^2) = g(1/2 + iz), \quad a_0 = g(1/2) > 0. \quad (5)$$

No square-root branch is part of the definition, and a_0 is not assigned the value one. The map $z \mapsto z^2$ identifies the two reflected coordinates only at this scalar-function observation; the original packet modules are retained in Section 5.

Define b_n by the analytic logarithmic derivative near zero:

$$-\frac{F'(w)}{F(w)} = \sum_{n \geq 0} b_n w^n. \quad (6)$$

The complete finite coefficient map is

$$b_n = \frac{-(n+1)a_{n+1} - \sum_{j=1}^n a_j b_{n-j}}{a_0}. \quad (7)$$

It follows by multiplying (6) by F and extracting the coefficient of w^n . For example,

$$b_0 = -\frac{a_1}{a_0}, \quad b_1 = \frac{a_1^2}{a_0^2} - \frac{2a_2}{a_0}, \quad b_2 = -\frac{a_1^3}{a_0^3} + \frac{3a_1 a_2}{a_0^2} - \frac{3a_3}{a_0}. \quad (8)$$

This operation need not preserve positivity of arbitrary coefficient sequences. The matrices used below are not positive by their definition.

242.4 3. A finite certificate contradicting RH

Let α_j be the distinct zeros of F , with their multiplicities m_j , and put $\beta_j = \alpha_j^{-1}$. These symbols are used to prove the test, not supplied to its numerical implementation.

Estimate (3), followed by $t = e^{2|y|}$, bounds the maximum modulus of g by an exponential of $O(R \log R)$. The maximum modulus of F at radius R is consequently bounded by an exponential of $O(\sqrt{R} \log R)$. Its order is at most $1/2 < 1$. Genus-zero Hadamard factorization therefore gives

$$F(w) = a_0 \prod_j (1 - \beta_j w)^{m_j}, \quad \sum_j m_j |\beta_j| < \infty. \quad (9)$$

There is no nonconstant exponential factor of integer degree at this order. Differentiating locally uniformly away from zeros proves

$$b_n = \sum_j m_j \beta_j^{n+1}. \quad (10)$$

The exact coordinate of a zeta zero $\rho = 1/2 + \delta + i\gamma$ is

$$z = -i(\rho - 1/2) = \gamma - i\delta, \quad \alpha = z^2 = \gamma^2 - \delta^2 - 2i\gamma\delta,$$

$$\beta = -\frac{1}{(\rho - 1/2)^2} = \frac{\gamma^2 - \delta^2 + 2i\gamma\delta}{(\gamma^2 + \delta^2)^2}. \quad (11)$$

The two reflected roots $\rho, 1 - \rho$ give one zero α of the same multiplicity in F . Conjugation gives the conjugate α and β .

For every real s , (1)–(3) give $g(s) = \int \psi(y) e^{(s-1/2)y} dy > 0$. Hence F has no nonpositive real zeros: $F(-v^2) = g(1/2 - v) > 0$. Thus RH is equivalent to every β_j being positive real.

For $d \geq 0$, define the actual Hankel coefficient matrix

$$H_d = (b_{r+s})_{0 \leq r, s \leq d}. \quad (12)$$

For $P(X) = \sum_{r=0}^d c_r X^r$ with real coefficients, the exact value is

$$c^T H_d c = \sum_j m_j \beta_j^2 P(\beta_j)^2. \quad (13)$$

Absolute convergence follows from (9) and boundedness of the polynomial on the compact set of reciprocal zeros and zero. Conjugate pairs make (13) real.

Under RH, each term is nonnegative. Therefore

$$c^T H_d c < 0 \implies \text{RH is false.} \quad (14)$$

The certificate may use $c \in \mathbb{Q}^{d+1}$: a strict negative value persists under sufficiently small rational coefficient perturbations. With validated enclosures $b_n \in [\underline{b}_n, \bar{b}_n]$, exact rational interval arithmetic on $\sum c_r c_s b_{r+s}$ is enough to certify that its upper endpoint is negative.

A second necessary family is $H_d^{(1)} = (b_{r+s+1})$. Under RH its quadratic form is $\sum_j m_j \beta_j^2 P(\beta_j)^2 \geq 0$. We tested both, though the unshifted family alone is complete by the next construction.

242.5 4. Work through the off-line counterfactual: construct its negative direction

Assume for this argument that RH is false. Equation (11) supplies a nonreal reciprocal zero β and its conjugate, each of multiplicity m . They are nonreal because g has no real zeros, so both γ and δ are nonzero.

Put $r = |\beta|/2$. There are finitely many distinct reciprocal zeros of modulus at least r . Remove $\beta, \bar{\beta}$ from that finite set and call the remaining set $\mathcal{A}$. It is closed under conjugation. Define the real polynomial

$$B(X) = \prod_{\gamma \in \mathcal{A}} (X - \gamma). \quad (15)$$

Choose $c \in \mathbb{C}$ satisfying $\beta c^2 = -1$; either of the two choices works. For an integer $N \geq 0$, put

$$w_N = \frac{c}{\beta^N B(\beta)}, \quad v_N = \frac{\operatorname{Im} w_N}{\operatorname{Im} \beta}, \quad u_N = \operatorname{Re} w_N - \operatorname{Re} \beta v_N,$$

$$\boxed{P_N(X) = X^N B(X)(\nu_N + v_N X).} \quad (16)$$

The coefficients are real. At the two target points,

$$P_N(\beta) = c, \quad P_N(\bar{\beta}) = \bar{c}.$$

At every other point of modulus at least r , P_N vanishes. The two target contributions to (13) are exactly

$$m\beta c^2 + m\bar{\beta} \bar{c}^2 = -2m. \quad (17)$$

Here is an explicit bound on everything else. Let

$$B_0 = \prod_{\gamma \in \mathcal{A}} (r + |\gamma|), \quad C = \frac{|c|B_0}{|B(\beta)|} \left(1 + \frac{|\operatorname{Re} \beta| + r}{|\operatorname{Im} \beta|} \right),$$

$$T = \sum_{|\beta_j| < r} m_j |\beta_j| < \infty.$$

For $|X| \leq r$, the coefficient definitions imply

$$|P_N(X)| \leq C \left(\frac{r}{|\beta|} \right)^N = C 2^{-N}.$$

Consequently the complete, real quadratic form satisfies

$$\boxed{\mathcal{L}(P_N^2) := \sum_j m_j \beta_j P_N(\beta_j)^2 \leq -2m + C^2 T 4^{-N}.} \quad (18)$$

For all sufficiently large N the right side is strictly negative. Every omitted reciprocal zero is included in the tail estimate, and every multiplicity is retained. This proves

$$\boxed{\text{RH} \iff H_d \succeq 0 \text{ for every } d \geq 0.} \quad (19)$$

It also explains the limitations of a finite search. The degree needed in (16) depends on the location of the off-line pair, the other larger reciprocal zeros, and the tail. The proof does not say that a counterexample must be visible in a small matrix. The polynomial (16) is a counterfactual construction; no actual off-line pair has been used to instantiate it.

242.6 5. Connect the witness to the original finite packet, including its jets

For a finite conjugation- and reflection-stable packet of actual zeros, retain the original inclusion

$$\sigma_h : E_h = \mathbb{C}[s]/(h) \hookrightarrow Q, \quad D_Q \sigma_h = \sigma_h A_h.$$

The original arithmetic input constructs this through the kernel of multiplication by $j_h g$. An arbitrary polynomial example is not automatically such a packet.

Because $g(1/2) > 0$, the operator $A_h - \frac{1}{2}I$ is invertible on every actual packet. Define the specified rational functional calculus

$$T_h = -(A_h - \frac{1}{2}I)^{-2}, \quad \mathbb{C}[X] \longrightarrow \text{End}_{\mathbb{C}}(E_h), \quad P \longmapsto P(T_h). \quad (20)$$

On a full local block $A_h = \rho I + N_\rho$, $N_\rho^m = 0$, the matrix is exactly

$$T_h = \sum_{j=0}^{m-1} (-1)^{j+1} (j+1) (\rho - 1/2)^{-j-2} N_\rho^j. \quad (21)$$

The coefficient of N_ρ is $2(\rho - 1/2)^{-3} \neq 0$, so this local coordinate change retains the nilpotent length. The two reflected primary modules can have the same T_h eigenvalue, but they remain separate in E_h .

The packet contribution to (13) is

$$\mathcal{L}_h(P^2) = \frac{1}{2} \text{Tr}_{E_h}(T_h P(T_h)^2). \quad (22)$$

The factor $1/2$ counts each reflected pair once, matching (5). The trace records algebraic multiplicities, while the full operators and their nilpotent coefficients remain upstream of the trace map. Absolute convergence in (9) makes the full functional the limit over packets exhausting the actual zero set.

The existing critical-line comparison satisfies

$$\ker(\Gamma \sigma_h) = E_{h,\text{off}}.$$

Equation (22) is evaluated on the source packet before applying that map. An off-critical class maps to $(\ell, 0)$ under the split lift of Γ , but is not deleted from the source on which the trace and negative witness are evaluated. This is why the search does not obtain a false positive or a false proof by restricting to the critical-only target.

242.7 6. The performed search uses the original theta seed, not zero ordinates

The numerical calculation uses (4), in the explicit form

$$M_{2j} = 4 \sum_{n \geq 1} \int_0^\infty y^{2j} \left(4\pi^2 n^4 e^{9y/2} - 6\pi n^2 e^{5y/2} \right) e^{-\pi n^2 e^{2y}} dy. \quad (23)$$

The factor four consists of the source theta factor two and the reflection factor two. The implementation computes $M_0, \dots, M_{64}$, forms (7), and tests both matrix families through dimension 16 by an unpivoted LDL^T calculation in their original monomial coordinates. No rescaling or preconditioning is used. No zero ordinate is supplied.

Two runs were completed:

Working decimal precision	Gauss–Legendre nodes	Retained theta terms	y interval	Outcome
120	384	12	[0,4]	All 16 pivots positive numerically, in both families
180	768	14	[0,4]	Same outcome

Selected values are

$$a_0 = 0.9942415563766282198255474793707954396 \dots,$$

$$b_0 = 0.0231049931154189707889338104303390140 \dots,$$

$$b_1 = 0.00003717259928526968616486626247174057845 \dots,$$

$$b_2 = 0.0000001441739314009732796953815560948209 \dots,$$

$$\det H_1 = b_0 b_2 - b_1^2 = 1.949335554819142214739878219172139506 \times 10^{-9} \dots$$

The largest relative difference between the two runs' stored pivot values is below 3×10^{-79} . Those stored values contain 80 significant digits, so the comparison does not support a stronger precision claim. The scripts report the input choices and complete pivot sequences.

These are exploratory multiple-precision quadratures, not interval-certified integrations. A failed attempt to install an interval-arithmetic backend did not produce an interval certificate; only the documented mpmath computations are reported. Positive numerical pivots do not prove the corresponding signs, and a negative numerical pivot would require certified analytic enclosures before it could count as a disproof. No negative numerical pivot was found.

242.8 7. Finite verification and the next decisive object

Six standard-library exact rational checks passed in normal and optimized Python. They verify the logarithmic recurrence, positive-node identity, an explicit nonreal-pair negative control, and a rational interval evaluator that cannot call an interval containing zero strictly negative. The negative control is expressly an auxiliary polynomial, not an actual zeta packet.

The interval evaluator's contract is limited: it checks the quadratic form from supplied valid intervals. Establishing that those intervals enclose the actual b_n remains an analytic task. No Lean certificate is claimed.

The decisive counterexample object in this branch is now a finite tuple

$$(d, c_0, \dots, c_d, [b_0, \bar{b}_0], \dots, [b_{2d}, \bar{b}_{2d}])$$

with rational c_r , rigorously justified coefficient enclosures from the original theta input, and a strictly negative upper bound for $\sum_{r,s} c_r c_s b_{r+s}$. Equation (14) proves exactly what that tuple would establish. Equation (18) proves that every actual off-line counterexample has a finite witness of this type at some degree.

The calculation performed here did not find that tuple. The failure of the previous auxiliary-purity inference is not used as evidence that one exists. Geometry over the original absolute base remains a

separate possible source of further constraints; this note establishes no impossibility theorem about it.

242.9 Source and execution record

- Original arithmetic source: supplied `arithmetic_input.tex`, equations (A1)–(A10), including the actual multiplication-by- $j_h g$ kernel sequence.
- Original support reconstruction and internal homology: supplied SplitZero reconstruction record, Sections 1–4. The source-labelled zero and the external absent value are kept distinct throughout.
- Original critical comparison: supplied `HOCHSCHILD_COMPARISON.md`, equations (H16)–(H25). The visible text supplies the exact off-critical kernel and critical-jet retractions.
- Prior scope: supplied `Tau_Deligne_Bound_Audit/NOTE.tex`, “Result and scope”. It explicitly does not refute the split-zero construction or establish falsity of the arithmetic estimate for 2ξ .
- Classical context: R. Zhang, *On Power Sums of Positive Numbers*, arXiv:1510.03420 (2015). Its abstract documents moment-theoretic positivity criteria for genus-zero entire functions and applications to RH. The concrete criterion and separation proof above are proved here, not attributed as a verbatim theorem from an uninspected full text.
- Classical background: Hadamard factorization for entire functions of order less than one; the functional equation and completed-zeta notation are also recorded in NIST DLMF Section 25.4. The source Gaussian estimate above supplies the order bound needed for this application.
- Computation: `mpmath 1.3.0`. Results are in `probe_120dps.json` and `probe_180dps.json`; reproduction script is `search_theta_moments.py`. Exact finite checks and the interval-input verifier are in `exact_witness_checks.py`.

No GitHub file, branch, comment, or remote publication was changed in this continuation.

243 Certified original-theta Hankel calculation

This calculation certifies strict positive definiteness of both original matrices

$$H_{15} = (b_{r+s})_{0 \leq r, s \leq 15}, \quad H_{15}^{(1)} = (b_{r+s+1})_{0 \leq r, s \leq 15}. \quad (\text{CH.1})$$

Their coefficients are computed from the original $g = 2\xi$ theta source. Every one of their 32 leading principal minors is certified positive. The coordinates, original mass, theta terms and logarithmic coefficient recurrence are retained. No zero ordinate is supplied to the calculation.

243.1 1. Original integral and coefficients

Use the original functions

$$\phi_*(x) = (4\pi^2 x^4 - 6\pi x^2)e^{-\pi x^2}, \quad f_0(x) = 2 \sum_{n \geq 1} \phi_*(nx), \quad \psi(y) = e^{y/2} f_0(e^y). \quad (\text{CH.2})$$

For completeness, write $\vartheta(x) = \sum_{n \in \mathbb{Z}} e^{-\pi n^2 x^2}$ and $D = -x\partial_x$. Termwise differentiation on compact positive x -intervals gives $f_0 = (D^2 - D)\vartheta$. The original Gaussian Poisson identity is $\vartheta(x) = x^{-1}\vartheta(1/x)$. For the exact reflection operator $(\mathcal{R}v)(x) = x^{-1}v(1/x)$, differentiation gives $D\mathcal{R} = \mathcal{R}(1 - D)$, and hence $(D^2 - D)\mathcal{R} = \mathcal{R}(D^2 - D)$. Applying this identity to ϑ proves $f_0(x) = x^{-1}f_0(1/x)$ and therefore $\psi(-y) = \psi(y)$. All powers of x are retained in this map. Consequently, for every even nonnegative integer J ,

$$\begin{aligned} M_J &= \int_{\mathbb{R}} y^J \psi(y) dy \\ &= \int_0^\infty y^J \sum_{n \geq 1} \left(16\pi^2 n^4 e^{9y/2} - 24\pi n^2 e^{5y/2} \right) e^{-\pi n^2 e^{2y}} dy. \end{aligned} \quad (\text{CH.3})$$

Both factors two, from theta summation and reflection, are present. Every summand in (CH.3) is nonnegative for $y \geq 0$, and is strictly positive for $y > 0$: its non-polynomial coefficient factors as

$$8\pi n^2 e^{5y/2} (2\pi n^2 e^{2y} - 3) e^{-\pi n^2 e^{2y}} > 0. \quad (\text{CH.4})$$

For $J = 0$, positivity holds at $y = 0$ as well.

The Mellin substitution $x = e^y$, including $dx = e^y dy$, gives

$$g(1/2 + iz) = \int_{\mathbb{R}} \psi(y) e^{izy} dy, \quad a_j = \frac{(-1)^j M_{2j}}{(2j)!}, \quad F(w) = \sum_{j \geq 0} a_j w^j. \quad (\text{CH.5})$$

The bounds proved below supply absolute integrability after multiplication by every power of y , and by $e^{A|y|}$ for each fixed A : replace $9/2$ by $9/2 + A$ in (CH.11) and choose a sufficiently large positive L , so its decay constant is positive. Reflection gives the same estimate on the other half-line. Thus dominated differentiation on compact z -sets is valid and proves $F(z^2) = g(1/2 + iz)$ with the displayed coefficients. In particular the original $a_0 = M_0 = g(1/2)$ is strictly positive. Multiplication of the convergent power series $-F'(w)/F(w) = \sum_{n \geq 0} b_n w^n$ by $F(w)$ gives

$$a_0 b_n + \sum_{j=1}^n a_j b_{n-j} = -(n+1)a_{n+1}, \quad b_n = \frac{-(n+1)a_{n+1} - \sum_{j=1}^n a_j b_{n-j}}{a_0}. \quad (\text{CH.6})$$

This is the exact coefficient map used by the program. The denominator is the computed interval for the original a_0 . It is never replaced by one.

243.2 2. Explicit positive omitted regions

Fix $N = 20$ and $L = 4$. The finite integral retains precisely $1 \leq n \leq 19$ and $0 \leq y \leq 4$. Its complement is the disjoint union of the omitted terms $n \geq 20$ on $0 \leq y \leq 4$ and every $n \geq 1$ on $y > 4$. Endpoints have measure zero.

For $n = N + \ell$, $\ell \geq 0$, the elementary inequality $\log(1 + t) \leq t$ for $t \geq 0$, proved by differentiating $t - \log(1 + t)$, implies

$$(N + \ell)^4 \leq N^4 e^{4\ell/N}, \quad (N + \ell)^2 \geq N^2 + 2N\ell. \quad (\text{CH.7})$$

Hence, for $y \geq 0$,

$$\sum_{n \geq N} n^4 e^{-\pi n^2 e^{2y}} \leq N^4 e^{-\pi N^2} \sum_{\ell \geq 0} e^{(4/N - 2\pi N)\ell} = \frac{N^4 e^{-\pi N^2}}{1 - e^{4/N - 2\pi N}}. \quad (\text{CH.8})$$

The exponent $4/N - 2\pi N$ is negative for every integer $N \geq 1$. Using (CH.4), and bounding the positive difference in (CH.3) by its first positive term, the first omitted region lies in $[0, T_{J,n}]$, where

$$T_{J,n} = \frac{16\pi^2 L^{J+1} e^{9L/2} N^4 e^{-\pi N^2}}{1 - e^{4/N - 2\pi N}}. \quad (\text{CH.9})$$

Indeed $y^J \leq L^J$ and $e^{9y/2} \leq e^{9L/2}$ on the finite interval, whose length contributes the displayed factor L . The deliberately larger bound L^{J+1} is retained.

For the second omitted region the same argument, with $N = 1$ but retaining the y -dependent first exponential, gives

$$\sum_{n \geq 1} n^4 e^{-\pi n^2 e^{2y}} \leq \frac{e^{-\pi e^{2y}}}{1 - e^{4 - 2\pi}}, \quad y \geq 0. \quad (\text{CH.10})$$

Set $h_J(y) = y^J e^{9y/2 - \pi e^{2y}}$ on $y \geq L > 0$. Its logarithmic derivative is

$$\frac{h'_J(y)}{h_J(y)} = \frac{J}{y} + \frac{9}{2} - 2\pi e^{2y} \leq -\alpha_J, \quad \alpha_J = 2\pi e^{2L} - \frac{9}{2} - \frac{J}{L}. \quad (\text{CH.11})$$

For $0 \leq J \leq 64$, $N = 20$, $L = 4$, all α_J are strictly positive. For example, $\pi > 3$ and $e^8 > 1 + 8 + 8^2/2 = 41$ give $\alpha_J > 246 - 9/2 - 16 > 0$. Integration of (CH.11) gives $h_J(y) \leq h_J(L) e^{-\alpha_J(y-L)}$, and then

$$T_{J,y} = \frac{16\pi^2 L^J e^{9L/2 - \pi e^{2L}}}{(1 - e^{4 - 2\pi})(2\pi e^{2L} - 9/2 - J/L)} \quad (\text{CH.12})$$

bounds the second omitted region. Therefore the complete exact moment satisfies

$$M_J \in I_{J,\text{finite}} + [0, T_{J,n} + T_{J,y}]. \quad (\text{CH.13})$$

The constants and signs of both original terms survive (CH.3) and the finite integration. The positive upper majorant is used only for the two explicitly omitted regions.

243.3 3. Validated finite integration and its exact export

The program uses python-flint 0.9.0, linked to FLINT 3.6.0, with 1024-bit arithmetic. For each even $J = 0, 2, \dots, 64$, it evaluates

$$z^J e^{z/2} \sum_{n=1}^{19} (16(\pi n^2 e^{2z})^2 - 24\pi n^2 e^{2z}) e^{-\pi n^2 e^{2z}}. \quad (\text{CH.14})$$

This is algebraically identical to the finite integrand in (CH.3). It is an entire complex function: all powers are nonnegative integer powers, and every remaining operation is addition, multiplication or the entire exponential. It has no branch cut, pole, absolute value, conjugation or piecewise real continuation.

The `acb.integral` callback receives a Boolean `analytic`. The official contract requires the callback to establish analyticity on the input complex ball when this flag is true. Formula (CH.14) is entire, so the same formula is valid for both values of the flag on every ball. This is the reason that the implementation may ignore the flag. It is not assuming that analyticity along the real segment alone suffices.

The finite interval is divided at the exact rationals $0, 1/2, 1, \dots, 7/2, 4$. Each of its eight integrals is evaluated with relative and absolute tolerance goals 2^{-850} , evaluation limit 200000 and depth limit 50. These controls affect effort and enclosure width; the final proof uses the returned enclosures themselves. Every returned value must be finite and its imaginary part must contain zero. Its real interval therefore encloses the real integral. The eight real intervals are added with outward rounding.

The two tail formulas are evaluated with Arb arithmetic, after verifying strict positivity of each denominator interval. If their sum has upper endpoint U_J , the program forms the interval $\text{hull}(0, U_J)$, and adds it to the real finite interval. This proves (CH.13) with the actually stored enclosure.

For every reported Arb ball, `lower()` and `upper()` produce exact dyadic endpoints rounded respectively downward and upward. `man_exp()` writes each as $m2^e$, with integers m, e . The export writes that same rational as numerator $m2^e$ and denominator one if $e \geq 0$, and numerator m , denominator 2^{-e} otherwise. No decimal conversion intervenes. Every decimal display field is for reading only. The lower and upper integer fractions are the authoritative certificate. The program raises the Python integer-string limit to accommodate the large dyadic denominator of (CH.12); this changes only serialization capacity.

243.4 4. Interval coefficient and LDL proof

Arb interval operations enclose every real operation on represented inputs. Induction in (CH.6), beginning with $a_0 > 0$, therefore proves that each stored a_j encloses the exact coefficient in (CH.5) and each stored b_n encloses the exact logarithmic coefficient in (CH.6). The 33 moments determine $a_0, \dots, a_{32}$ and $b_0, \dots, b_{31}$, exactly the data required by (CH.1).

For each shift $\epsilon = 0, 1$, put $A_{ij} = b_{i+j+\epsilon}$. In the original ordered monomial basis, define the unit lower triangular matrix L and diagonal $D = \text{diag}(d_0, \dots, d_{15})$ recursively by

$$d_j = A_{jj} - \sum_{k < j} L_{jk}^2 d_k, \quad L_{ij} = \frac{A_{ij} - \sum_{k < j} L_{ik} L_{jk} d_k}{d_j} \quad (i > j). \quad (\text{CH.15})$$

The implementation checks that the entire computed interval for d_j is strictly positive before every division. Induction on j proves that the stored interval values contain the exact values of (CH.15). The equations for the diagonal and lower triangular entries are exactly the equations of $A = LDL^T$; symmetry supplies the upper triangular entries. Since L is invertible with determinant one,

$$c^T A c = \sum_{j=0}^{15} d_j (L^T c)_j^2 > 0 \quad \text{for every } c \in \mathbb{R}^{16} \setminus \{0\}. \quad (\text{CH.16})$$

For each leading size r , restriction to the first r coordinates and triangularity give

$$\det A_{[0, r-1]} = \prod_{j=0}^{r-1} d_j > 0. \quad (\text{CH.17})$$

The exact interval computation certifies all 32 pivots as positive. No pivoting, coordinate rescaling, diagonal congruence or replacement of the source mass occurs.

243.5 5. Recorded values and finite conclusion

The authoritative file `certificate_dimension16_1024.json` stores all 264 finite integral pieces, their real and imaginary intervals, all 66 tail bounds, all 33 complete moments, all coefficients, and both complete lower triangular factor intervals. The run took about 16.14 seconds on the recorded host. This duration measures one reproducible computation, rather than a mathematical assumption.

For orientation the original mass and first coefficients begin

$$\begin{aligned} a_0 &= 0.99424155637662821982554747937079544 \dots, \\ b_0 &= 0.023104993115418970788933810430339014 \dots, \\ b_1 &= 3.7172599285269686164866262471740578 \dots \times 10^{-5}, \\ b_2 &= 1.4417393140097327969538155609482091 \dots \times 10^{-7}. \end{aligned} \tag{CH.18}$$

The last pivots and full determinants are enclosed within the following simple rational intervals:

$$\begin{array}{c|c|c} \epsilon & d_{15} & \det H_{15}^{(\epsilon)} \\ \hline 0 & (6 \cdot 10^{-107}, 7 \cdot 10^{-107}) & (9 \cdot 10^{-822}, 10 \cdot 10^{-822}) \\ 1 & (7 \cdot 10^{-111}, 8 \cdot 10^{-111}) & (6 \cdot 10^{-878}, 7 \cdot 10^{-878}) \end{array} \tag{CH.19}$$

The exact stored rational endpoints are much narrower; the respective last pivots retain 656 and 648 relative accuracy bits.

Thus this calculation establishes strict positivity of the two specified dimension-16 matrices and every leading truncation. Its quantified conclusion concerns these finite matrices. It supplies certified original-theta inputs in place of the Workbench’s unvalidated quadrature values at these dimensions.

243.6 Reproduction

Run `certify_theta_hankel.py` with arguments `--dimension 16 --precision 1024 --target-bits 850 --output certificate_dimension16_1024.json` using `python-flint 0.9.0`. The defaults retain $N = 20$, $L = 4$. The file `certificate_dimension2_256.json` records a separate smaller run with dimension two, precision 256 and tolerance exponent 200.

The official integration and real-endpoint API contracts are documented at:

- [python-flint complex integration](#)
- [python-flint real ball endpoints](#)

The local `API_CONTRACT.txt` records the installed method docstrings used when implementing the computation.

244 Independent theta-tail proof and certificate code review

Date: 2026-09-13.

This review concerns the exact original theta integrand, its omitted tails, and the complete code path that produces the dimension-16 logarithmic Hankel certificate. It retains every coefficient in the integrand. The parent is independently replaying the rational interval arithmetic; this review supplies the analytic proof and an independent complete source read.

244.1 1. Exact objects and retained integral

Let J be a nonnegative integer, N a positive integer, and $L > 0$. For $n \geq 1$ and real $y \geq 0$, set

$$f_{J,n}(y) = y^J \left(16\pi^2 n^4 e^{9y/2} - 24\pi n^2 e^{5y/2} \right) e^{-\pi n^2 e^{2y}}, \quad F_J(y) = \sum_{n=1}^{\infty} f_{J,n}(y). \quad (\text{TR1})$$

When $J = 0$, the factor y^0 is the constant function 1, including at zero. The intended integral and retained part are

$$I_J = \int_0^{\infty} F_J(y) dy, \quad I_{J,N,L}^{\text{fin}} = \int_0^L \sum_{n=1}^{N-1} f_{J,n}(y) dy. \quad (\text{TR2})$$

For $N = 1$, the finite sum is empty and its integral is zero. The actual run uses $N = 20$, $L = 4$, and $J = 0, 2, \dots, 64$; it therefore retains precisely $n = 1, \dots, 19$.

244.2 2. Positivity and the exact majorant

The identity

$$16\pi^2 n^4 e^{9y/2} - 24\pi n^2 e^{5y/2} = 8\pi n^2 e^{5y/2} (2\pi n^2 e^{2y} - 3) \quad (\text{TR3})$$

proves that the parenthesis in (TR1) is strictly positive, since $2\pi n^2 e^{2y} - 3 \geq 2\pi - 3 > 0$. Thus

$$0 \leq f_{J,n}(y) \leq 16\pi^2 y^J e^{9y/2} n^4 e^{-\pi n^2 e^{2y}}. \quad (\text{TR4})$$

The upper estimate discards a nonnegative subtracted term only in the estimate. Both terms remain in the actual finite integral.

For every $N \geq 1$,

$$0 < r_N := e^{4/N - 2\pi N} \leq r_* := e^{4 - 2\pi} < 1. \quad (\text{TR5})$$

Here $4/N \leq 4$, $N \geq 1$, and $\pi > 3$.

244.3 3. Omitted summands on the retained interval

Put $a_n = n^4 e^{-\pi n^2}$. Its exact consecutive-term ratio is

$$\frac{a_{n+1}}{a_n} = \left(1 + \frac{1}{n} \right)^4 e^{-\pi(2n+1)}. \quad (\text{TR6})$$

For $x \geq 0$, $\log(1+x) \leq x$: the difference $x - \log(1+x)$ is zero at zero and has derivative $x/(1+x) \geq 0$. Consequently, for $n \geq N$,

$$\begin{aligned} \log \frac{a_{n+1}}{a_n} &= 4 \log(1 + 1/n) - 2\pi n - \pi \\ &\leq 4/n - 2\pi n - \pi \\ &\leq 4/N - 2\pi N - \pi \leq 4/N - 2\pi N = \log r_N. \end{aligned} \quad (\text{TR7})$$

It follows by induction that $a_{N+j} \leq a_N r_N^j$ for every integer $j \geq 0$, and hence

$$\sum_{n=N}^{\infty} n^4 e^{-\pi n^2} \leq \frac{N^4 e^{-\pi N^2}}{1 - r_N}. \quad (\text{TR8})$$

On $0 \leq y \leq L$, use $y^J \leq L^J$, $e^{9y/2} \leq e^{9L/2}$, and $e^{-\pi n^2 e^{2y}} \leq e^{-\pi n^2}$. Equations (TR4) and (TR8) then give

$$\begin{aligned} 0 \leq E_{J,N,L}^{(n)} &:= \int_0^L \sum_{n=N}^{\infty} f_{J,n}(y) dy \\ &\leq \frac{16\pi^2 L^{J+1} e^{9L/2} N^4 e^{-\pi N^2}}{1 - e^{4/N-2\pi N}} =: T_n(J, N, L). \end{aligned} \quad (\text{TR9})$$

The extra negative term $-\pi$ in (TR7) was discarded in the direction that enlarges the upper bound. This proves the proposed expression with its stated denominator.

The same argument with $N = 1$ gives a summable uniform majorant on each compact interval $[0, L]$. The series defining F_J is therefore uniformly convergent there and continuous. Its summands are nonnegative, so monotone convergence also justifies the sum-integral interchanges above and below.

244.4 4. The complete integration tail

For fixed $y \geq 0$, write $a_n(y) = n^4 e^{-\pi n^2 e^{2y}}$. Then

$$\begin{aligned} \log \frac{a_{n+1}(y)}{a_n(y)} &= 4 \log(1 + 1/n) - \pi(2n+1)e^{2y} \\ &\leq 4/n - 2\pi n e^{2y} - \pi e^{2y} \\ &\leq 4 - 2\pi = \log r_*. \end{aligned} \quad (\text{TR10})$$

The last inequality uses $1/n \leq 1$, $n e^{2y} \geq 1$, and $-\pi e^{2y} \leq 0$. Since $a_1(y) = e^{-\pi e^{2y}}$, the geometric-series estimate is

$$\sum_{n=1}^{\infty} n^4 e^{-\pi n^2 e^{2y}} \leq \frac{e^{-\pi e^{2y}}}{1 - e^{4-2\pi}}. \quad (\text{TR11})$$

Therefore

$$0 \leq F_J(y) \leq \frac{16\pi^2}{1 - e^{4-2\pi}} y^J e^{9y/2 - \pi e^{2y}}. \quad (\text{TR12})$$

Define

$$A_{J,L} = 2\pi e^{2L} - \frac{9}{2} - \frac{J}{L}. \quad (\text{TR13})$$

When $A_{J,L} > 0$, the positive function $q_J(y) = y^J e^{9y/2 - \pi e^{2y}}$, for $y \geq L > 0$, satisfies

$$\frac{q'_J(y)}{q_J(y)} = \frac{J}{y} + \frac{9}{2} - 2\pi e^{2y} \leq \frac{J}{L} + \frac{9}{2} - 2\pi e^{2L} = -A_{J,L}. \quad (\text{TR14})$$

The first summand is identically zero for $J = 0$. Integrating this differential inequality gives $q_J(y) \leq q_J(L) e^{-A_{J,L}(y-L)}$. Thus

$$\begin{aligned} 0 \leq E_{J,L}^{(y)} &:= \int_L^{\infty} \sum_{n=1}^{\infty} f_{J,n}(y) dy \\ &\leq \frac{16\pi^2 L^J e^{9L/2 - \pi e^{2L}}}{(1 - e^{4-2\pi})(2\pi e^{2L} - 9/2 - J/L)} =: T_y(J, L). \end{aligned} \quad (\text{TR15})$$

This integral includes every $n \geq 1$, including all omitted summands $n \geq N$ beyond L .

244.5 5. The exact remainder and interval addition

The omitted domain is the disjoint union, up to the measure-zero endpoint slice, of

$$\{(n, y) : n \geq N, 0 \leq y < L\} \quad \text{and} \quad \{(n, y) : n \geq 1, L \leq y < \infty\}. \quad (\text{TR16})$$

The two integrals are nonnegative and finite by (TR9) and (TR15). They therefore give the exact identity and enclosure

$$I_J = I_{J,N,L}^{\text{fin}} + E_{J,N,L}^{(n)} + E_{J,L}^{(y)}, \quad I_J - I_{J,N,L}^{\text{fin}} \in [0, T_n + T_y]. \quad (\text{TR17})$$

There is no double counting of $n \geq N$ beyond L : that region occurs only in $E^{(y)}$. If $[a, b]$ encloses the finite integral and $\bar{T} \geq T_n + T_y$, then

$$I_J \in [a, b] + [0, \bar{T}] = [a, b + \bar{T}]. \quad (\text{TR18})$$

The entire interval $[0, \bar{T}]$, rather than a tail midpoint, is what must be added.

For the actual parameters the formulas are

$$\begin{aligned} T_n(J, 20, 4) &= \frac{16\pi^2 4^{J+1} e^{18} 20^4 e^{-400\pi}}{1 - e^{1/5-40\pi}}, \\ T_y(J, 4) &= \frac{16\pi^2 4^J e^{18-\pi e^8}}{(1 - e^{4-2\pi})(2\pi e^8 - 9/2 - J/4)}. \end{aligned} \quad (\text{TR19})$$

All denominator signs are proved exactly for $0 \leq J \leq 64$:

$$1/5 - 40\pi < -599/5 < 0, \quad 4 - 2\pi < -2 < 0, \quad (\text{TR20})$$

and $e^8 > 1 + 8 = 9$ gives

$$2\pi e^8 - \frac{9}{2} - \frac{J}{4} > 6 \cdot 9 - \frac{9}{2} - 16 = \frac{67}{2} > 0. \quad (\text{TR21})$$

Thus the claimed tail hypotheses are verified for every actual moment in the run, without a floating-point sign assumption.

244.6 6. Entire finite integrand and its literal code expression

For each nonnegative integer J , the function

$$z \mapsto z^J \sum_{n=1}^{N-1} (16\pi^2 n^4 e^{9z/2} - 24\pi n^2 e^{5z/2}) e^{-\pi n^2 e^{2z}} \quad (\text{TR22})$$

is entire on $\mathbb{C}$: the only operations are a polynomial, exponentials and their compositions, and finite sums and products. The code sets $x = \pi n^2 e^{2z}$ and evaluates

$$z^J e^{z/2} \sum_{n=1}^{N-1} (16x^2 - 24x) e^{-x}. \quad (\text{TR23})$$

The exact identities

$$16x^2 e^{z/2} = 16\pi^2 n^4 e^{9z/2}, \quad 24x e^{z/2} = 24\pi n^2 e^{5z/2} \quad (\text{TR24})$$

prove equality of (TR23) and (TR22). This rewrite retains the subtracted term and all original coefficients.

The installed python-flint 0.9.0 documentation for `acb.integral` was read directly. Its callback receives a complex ball and an analytic flag. When that flag is true, the callback must establish analyticity on the ball or return a nonfinite ball. The entire function (TR22) meets this requirement on every complex ball, so ignoring that flag in this particular callback is justified by the proof above. There are no fractional powers, logarithms, branches, or pole-containing denominators in the callback.

The code uses `arb.pi()` and integer arithmetic for its coefficients. Every division appearing in the callback or integration endpoints is performed on an `Arb/Acb` object and an exact integer. The finite path is partitioned into the eight consecutive exact intervals $[j/2, (j+1)/2]$, $j = 0, \dots, 7$. Their union is exactly $[0, 4]$. The code rejects nonfinite integrals and any reported imaginary enclosure excluding zero, then sums the complex balls. Since the exact integral is real, its real-part enclosure contains (TR2). The tolerance is an exact dyadic 2^{-850} ; the working precision is 1024 bits. The elapsed-time floats do not enter the mathematics.

244.7 7. Complete tail-code and exact-export review

The function `positive_tails` computes precisely (TR9), (TR15), and (TR13), with outward-rounded `Arb` operations. It explicitly rejects any run that fails to certify $1 - r_N > 0$, $1 - r_* > 0$, or $A_{J,L} > 0$. It uses the original factor $16\pi^2$ in each tail.

The function `compute_moment` takes the outward upper endpoint of the sum of the two tail balls, forms the ball union of that endpoint with zero, and adds that union to the real finite-integral ball. An enclosing ball union can slightly enlarge the endpoint interval, but it contains the whole interval required by (TR18). It does not replace the nonnegative tail interval with its midpoint. The final strict-positive comparison certifies positivity of the whole resulting moment ball.

The installed `arb.lower` and `arb.upper` documentation was also read directly. These methods return exact finite floating-point numbers rounded respectively toward negative and positive infinity at the active precision. The installed `arb.man_exp` documentation says it requires an exact finite input and returns an integer mantissa m and integer exponent e . Therefore the exported endpoint is exactly

$$m2^e = \begin{cases} (m2^e)/1, & e \geq 0, \\ m/(2^{-e}), & e < 0. \end{cases} \quad (\text{TR25})$$

This is precisely the case distinction in `exact_dyadic`. Python integers and their decimal strings retain these numerators and denominators exactly. They need not be reduced to lowest terms to represent the same rational endpoint. The enclosing real interval exported by `enclosure` consequently retains a certified lower and upper rational bound; its shorter decimal display is additional presentation data.

The helper `from_enclosure` parses both endpoint fractions through `Arb` and unions their enclosures. This remains sound if rounding enlarges them. It is unused in the original integration and LDL run and therefore does not participate in the output's arithmetic chain.

244.8 8. Original logarithmic coefficient recurrence

Write $M_{2j} = I_{2j}$ for the original moments defined by (TR2). Define the exact formal series

$$A(z) = \sum_{j \geq 0} a_j z^j, \quad a_j = \frac{(-1)^j M_{2j}}{(2j)!}, \quad B(z) = -\frac{A'(z)}{A(z)} = \sum_{n \geq 0} b_n z^n. \quad (\text{TR26})$$

The nonzero constant term $a_0 = I_0 > 0$ is proved by (TR1), (TR3), and integration over any interval of positive length. Thus the formal division in (TR26) is uniquely defined, and no convergence

assumption is needed to compute its finite jet. The identity $A(z)B(z) = -A'(z)$, in degree n , is

$$a_0 b_n + \sum_{j=1}^n a_j b_{n-j} = -(n+1)a_{n+1}. \quad (\text{TR27})$$

Solving for b_n gives exactly the recurrence in `logarithmic_coefficients`:

$$b_n = \frac{-(n+1)a_{n+1} - \sum_{j=1}^n a_j b_{n-j}}{a_0}. \quad (\text{TR28})$$

The factorials and signs are Python integers; the divisions and sums occur in Arb arithmetic. Starting from enclosing moment balls, induction on n proves that the computed a_j and b_n balls contain the exact coefficients (TR26). The denominator ball is certified positive before division. Correlations between occurrences of earlier balls can enlarge the resulting intervals but cannot invalidate their containment.

For dimension $d = 16$, the loop integrates $J = 0, 2, \dots, 4d$, giving $2d + 1 = 33$ moments and $a_0, \dots, a_{32}$. The recurrence produces $b_0, \dots, b_{31}$. Both Hankel matrices

$$H^{(r)} = (b_{i+j+r})_{0 \leq i, j < 16}, \quad r \in \{0, 1\}, \quad (\text{TR29})$$

are therefore completely specified: their largest needed indices are 30 and 31. The code uses these exact indices. It introduces no rescaling of the coefficient sequence or matrix.

244.9 9. Unpivoted LDL proof and the meaning of positivity

Fix $r \in \{0, 1\}$. For the exact real symmetric matrix $H^{(r)}$, let L be lower triangular with diagonal entries 1 and define, in increasing order of j ,

$$\begin{aligned} d_j &= H_{jj}^{(r)} - \sum_{k=0}^{j-1} L_{jk}^2 d_k, \\ L_{ij} &= \frac{H_{ij}^{(r)} - \sum_{k=0}^{j-1} L_{ik} L_{jk} d_k}{d_j}, \quad i > j. \end{aligned} \quad (\text{TR30})$$

The code implements these exact ordered recurrences. At step j , every lower entry used in the sums was computed at an earlier step. Induction on j proves that the stored balls enclose the exact values: the initial coefficient balls enclose $H^{(r)}$; sums and products preserve enclosure; and every divisor interval is certified strictly positive before its use. Hence each exact $d_j > 0$.

To establish the matrix identity, for $i = j$, the first recurrence in (TR30) gives $(LDL^T)_{jj} = H_{jj}^{(r)}$; for $i > j$, the second gives $(LDL^T)_{ij} = H_{ij}^{(r)}$. Symmetry supplies the entries $i < j$. Thus

$$H^{(r)} = L \operatorname{diag}(d_0, \dots, d_{15}) L^T. \quad (\text{TR31})$$

Since L is unit lower triangular it is invertible. For every nonzero $v \in \mathbb{R}^{16}$, the vector $L^T v$ is nonzero, and

$$v^T H^{(r)} v = \sum_{j=0}^{15} d_j (L^T v)_j^2 > 0. \quad (\text{TR32})$$

This proves positive definiteness of each original unscaled matrix, once all 16 pivot intervals are positive. Restricting (TR31) to the first s indices gives the exact leading determinant

$$\det H_{[0,s]}^{(r)} = \prod_{j=0}^{s-1} d_j, \quad 1 \leq s \leq 16, \quad (\text{TR33})$$

which is the interval product saved in each row. The unsuccessful branch reports `positivity_not_certified` rather than asserting that the matrix is indefinite. A finite useful certificate is produced only after all divisions used in it have positive divisor intervals.

244.10 10. Reviewed source and observed certificate

The complete 163-line source was read, including argument validation, partial-file writes, numerical functions, serialization, final status, and both matrix calls. The file reviewed is `certify_theta_hankel.py`, SHA-256:

a97486edc2fc1f05f155a9539ad280433be39a8f6924efbc8c1c1c4d71033950

The inspected certificate is `certificate_dimension16_1024.json`, SHA-256:

869ebacd3f82e46c3fe5fac1f07bcbaae7f4c333e1a5ba2e0ffcb1f91884a0fc

Its `source_sha256` equals the independently hashed reviewed source. It records python-flint 0.9.0, 1024-bit working precision, 850 target bits, dimension 16, $N = 20$, and $L = 4$. It contains all 33 required moments, eight finite-integration pieces per moment, 33 coefficient a intervals, 32 coefficient b intervals, and 16 successful pivot rows for each $r = 0, 1$. Its final status is `positive_definite_certified`.

The certificate's displayed dimension-16 endpoints, quoted here only as orientation while exact dyadic endpoints remain authoritative, are approximately:

Matrix	Last pivot		Full determinant
$H^{(0)}$	6.1698420811114408502314906319786538 ×	10^{-107}	9.2735841166129968999872729909592731 ×
			10^{-822}
$H^{(1)}$	7.1026100619440799659087832255229554 ×	10^{-111}	6.3606810193647631787476650057683745 ×
			10^{-878}

244.11 11. Acceptance and scope of the completed proof

Both proposed tail formulas are valid with every original constant. The analytic callback meets its contract, the retained summand matches the original expression exactly, the code adds the required nonnegative tail interval, the endpoint export is exact rational, the logarithmic recurrence has the correct signs and indices, and the LDL recurrences certify the original two matrices. This review found no formula/code mismatch and no correction necessary for the inspected dimension-16 run.

The exact objects certified are the moments (TR2), the finite logarithmic jet (TR26), and the two finite matrices (TR29). Their positive definiteness gives every leading determinant through dimension 16 by (TR33). Identifying a separately defined zeta function with A , or passing from these finite matrices to an assertion covering every dimension, requires the corresponding exact map and argument in the surrounding research; neither further statement is silently inserted into this certificate. The completed tail and finite-matrix calculations themselves use no zero ordinates, off-line zero assumption, or unproved infinite-dimensional positivity assertion.

245 Independent verification of the positive theta tails

Date: 2026-09-13. The complete file `theta_certified_hankel_20260913/certify_theta_hankel.py` was read. Its SHA-256 is `a97486edc2fc1f05f155a9539ad280433be39a8f6924efbc8c1c1c4d71033950`. This review verifies the two formulas in `positive_tails` and the finite integration callback's analyticity. It does not rerun integration or review the separately assigned logarithmic recurrence, dyadic export, and LDL calculation.

Finding: both tail bounds are valid upper bounds with the printed constants, and the omitted integrand is nonnegative. For $N = 20, L = 4, J \in \{0, 2, \dots, 64\}$, all three denominator signs are strictly positive. No correction is required.

245.1 1. Exact integrand and the disjoint omitted regions

For $y \geq 0, n \geq 1$, and nonnegative integer J , write

$$x_n(y) = \pi n^2 e^{2y}, \quad f_{J,n}(y) = y^J e^{y/2} (16x_n(y)^2 - 24x_n(y)) e^{-x_n(y)}. \quad (\text{TT1})$$

For $J = 0$, the polynomial y^0 is identically one, including at zero. The finite callback integrates $\sum_{n=1}^{N-1} f_{J,n}$ on $[0, L]$. Its omitted part is exactly

$$\int_0^L \sum_{n=N}^{\infty} f_{J,n}(y) dy + \int_L^{\infty} \sum_{n=1}^{\infty} f_{J,n}(y) dy. \quad (\text{TT2})$$

The shared boundary has measure zero. There is no extra multiplicity or factor of two in this decomposition of the literal half-line integral.

Since $x_n(y) \geq \pi > 3/2$,

$$0 < 16x_n(y)^2 - 24x_n(y) \leq 16x_n(y)^2.$$

Consequently

$$0 \leq f_{J,n}(y) \leq 16\pi^2 n^4 y^J \exp\left(\frac{9}{2}y - \pi n^2 e^{2y}\right). \quad (\text{TT3})$$

The factor $9/2$ is the exact sum $4 + 1/2$ coming from $x_n(y)^2$ and $e^{y/2}$. The negative $-24x_n$ is retained in the finite callback; dropping it only increases the omitted-tail majorant.

245.2 2. Omitted n -sum on $0 \leq y \leq L$

On this interval, $y^J \leq L^J$, $e^{9y/2} \leq e^{9L/2}$, and $e^{-\pi n^2 e^{2y}} \leq e^{-\pi n^2}$. Therefore the first term in (TT2) is at most

$$16\pi^2 L^{J+1} e^{9L/2} \sum_{n=N}^{\infty} n^4 e^{-\pi n^2}. \quad (\text{TT4})$$

For $a_n = n^4 e^{-\pi n^2}$, the exact ratio and its majorant satisfy, for every $n \geq N$,

$$\begin{aligned} \frac{a_{n+1}}{a_n} &= (1 + 1/n)^4 e^{-\pi(2n+1)} \\ &\leq e^{4/n - \pi(2n+1)} \leq e^{4/N - 2\pi N} =: \rho_n. \end{aligned} \quad (\text{TT5})$$

The first inequality uses $\log(1 + 1/n) \leq 1/n$. The second drops the additional negative term $-\pi$ and uses $1/n \leq 1/N$ and $n \geq N$. If $\rho_n < 1$, induction gives $a_{N+j} \leq a_N \rho_n^j$, hence

$$0 \leq \int_0^L \sum_{n=N}^{\infty} f_{J,n}(y) dy \leq \frac{16\pi^2 L^{J+1} e^{9L/2} N^4 e^{-\pi N^2}}{1 - e^{4/N-2\pi N}} =: T_n. \quad (\text{TT6})$$

This is exactly the returned expression tn , including its first omitted index N and denominator.

245.3 3. Omitted y -interval, including every $n \geq 1$

For fixed $y \geq 0$, let $a_n(y) = n^4 e^{-\pi n^2 e^{2y}}$. For every $n \geq 1$,

$$\begin{aligned} \frac{a_{n+1}(y)}{a_n(y)} &= (1 + 1/n)^4 e^{-\pi(2n+1)e^{2y}} \\ &\leq e^{4/n-2\pi n e^{2y}} \leq e^{4-2\pi e^{2y}} \leq e^{4-2\pi} =: \rho_y. \end{aligned} \quad (\text{TT7})$$

Thus

$$\sum_{n=1}^{\infty} n^4 e^{-\pi n^2 e^{2y}} \leq \frac{e^{-\pi e^{2y}}}{1 - \rho_y}.$$

Combining this with (TT3), the second omitted integral in (TT2) is at most

$$\frac{16\pi^2}{1 - \rho_y} \int_L^{\infty} F_J(y) dy, \quad F_J(y) = y^J e^{9y/2 - \pi e^{2y}}. \quad (\text{TT8})$$

For $L > 0$, F_J is positive on $[L, \infty)$. Its logarithmic derivative is exactly

$$\frac{F'_J(y)}{F_J(y)} = \frac{J}{y} + \frac{9}{2} - 2\pi e^{2y} \leq \frac{J}{L} + \frac{9}{2} - 2\pi e^{2L} = -\delta, \quad \delta := 2\pi e^{2L} - \frac{9}{2} - \frac{J}{L}. \quad (\text{TT9})$$

Both inequalities have the displayed direction because $J \geq 0$, $y \geq L > 0$, and the exponential is increasing. When $\delta > 0$, integrating (TT9) from L to y gives $F_J(y) \leq F_J(L) e^{-\delta(y-L)}$. Integrating this inequality proves

$$0 \leq \int_L^{\infty} \sum_{n=1}^{\infty} f_{J,n}(y) dy \leq \frac{16\pi^2 L^J e^{9L/2 - \pi e^{2L}}}{(1 - e^{4-2\pi})(2\pi e^{2L} - 9/2 - J/L)} =: T_y. \quad (\text{TT10})$$

This is exactly ty and its returned decay denominator. The constant geometric majorant ρ_y is deliberately larger than the y -dependent ratio; using it cannot underestimate the tail.

The bounds also justify integrability of the positive series. Tonelli's theorem permits the nonnegative sums and integrals throughout; (TT6) and (TT10), together with the finite continuous integral, show their total is finite.

245.4 4. Denominator signs at the actual parameters

For $N = 20$, $L = 4$, and every stated $J \leq 64$, the elementary inequalities $\pi > 3$ and $e^8 > 1 + 8 = 9$ give

$$\begin{aligned} \frac{4}{N} - 2\pi N &< \frac{1}{5} - 120 = -\frac{599}{5}, \\ 4 - 2\pi &< -2, \\ \delta = 2\pi e^8 - \frac{9}{2} - \frac{J}{4} &> 54 - \frac{9}{2} - 16 = \frac{67}{2} > 0. \end{aligned} \quad (\text{TT11})$$

Hence $1 - \rho_n > 1 - e^{-599/5} > 0$, $1 - \rho_y > 1 - e^{-2} > 0$, and $\delta > 67/2$. These are proved lower bounds for the exact denominators at every required even J ; evenness is not needed for the estimates.

The code independently requires the Arb comparisons for those signs to succeed. All quantities in T_n, T_y are nonnegative, and the omitted part lies in $[0, T_n + T_y]$. Therefore using the upper endpoint of the computed enclosure of $tn+ty$ and taking its interval hull with zero gives the correct one-sided tail enclosure. This conclusion uses the printed real interval operations and the exact inequalities above; it does not assert that this review executed those operations.

245.5 5. Callback analyticity

The finite callback, as a function of complex y , is

$$y^J e^{y/2} \sum_{n=1}^{N-1} (16\pi^2 n^4 e^{4y} - 24\pi n^2 e^{2y}) \exp(-\pi n^2 e^{2y}). \quad (\text{TT12})$$

Every power y^J has a nonnegative integer exponent. All other operations are finite sums, products, and compositions of exponential functions. The function is therefore entire, including at $y = 0$ and for $J = 0$. It uses no conjugation, absolute value, logarithm, division by y , or noninteger power. Accordingly the `analytic=True` callback branch requires no restriction of its complex domain.

The value returned for a complex ball encloses the expression using the real Arb enclosure of π . For each fixed coefficient value within that enclosure, the same finite expression is entire; in particular the target with the exact constant π is entire. Possible nonfinite numerical enclosures do not create an analytic singularity, and the caller separately rejects a nonfinite integration result.

The program partitions $[0, 4]$ into the eight exact half-unit subintervals with endpoints $j/2, (j + 1)/2$. The omitted regions and the denominators proved above match that finite integration interval and the loop $n=1, \dots, 19$ exactly. This review accepts the tail formulas and callback analyticity without rerunning that integration.

246 Independent review of the theta error bounds and finite rational witness

Date: 2026-09-13. The complete source tau_theta_hankel_error_control_20260913.tex, TC1–TC28, was read at SHA-256 55f7a9cce6f22b11a30321a7ba726f300a990e78c39780a43b7fdd692c7935e5. This review independently checks the tail estimates, finite algebra, explicit degree cutoff, coefficient rounding, and interval detection of a negative witness. The integration was not rerun, and the source was not edited.

Finding. The mathematical formulas TC1–TC26 are consistent with the retained source identities, and TC23 and TC25 give the claimed margins, including their endpoint cases. The finite positive-definiteness implication in TC27 follows from the stated exact pivot certificates; their complete numerical endpoint replay is the separate parent review. The displayed TC28 decimal enclosure matches its display string in certificate_dimension16_1024.json.

One prose correction was reported: “No coefficient is removed by the rounding rule” can be read as asserting that a nonzero coefficient never rounds to zero, which is false. The precise statement is: every original coefficient slot is included in the error estimate; nearest-grid rounding may produce zero. The theorem should explicitly specify rounding to a nearest multiple of $1/H$, with either choice allowed at a tie. These changes clarify the already used bound $1/(2H)$; no displayed inequality needs alteration.

246.1 1. Retained integral and complete positive tail bounds

The review uses the workbench’s original reflection and Mellin identities stated before TC2, with $g = 2\xi$. There are two distinct factors of two: one in $f_0 = 2 \sum \phi_*$, and one from reflection of the even moment. Their product gives the factor four in TC2. Expanding

$$y^J e^{y/2} (16x_n^2 - 24x_n) e^{-x_n}, \quad x_n = \pi n^2 e^{2y},$$

gives exactly

$$4y^J (4\pi^2 n^4 e^{9y/2} - 6\pi n^2 e^{5y/2}) e^{-\pi n^2 e^{2y}}. \quad (\text{TR1})$$

Thus TC2 and the callback TC9 agree with their original constants.

For $y \geq 0, n \geq 1, x_n \geq \pi > 3/2$, so

$$0 \leq y^J e^{y/2} (16x_n^2 - 24x_n) e^{-x_n} \leq 16\pi^2 n^4 y^J e^{9y/2 - \pi n^2 e^{2y}}. \quad (\text{TR2})$$

For the polynomial y^0 , its value at zero is one. For $J > 0$, the vanishing factor at zero creates no exception to the inequality.

For $n = N + \ell, \ell \geq 0$, the elementary bounds $(N + \ell)^4 \leq N^4 e^{4\ell/N}$ and $(N + \ell)^2 \geq N^2 + 2N\ell$ imply

$$\sum_{n=N}^{\infty} n^4 e^{-\pi n^2 e^{2y}} \leq \frac{N^4 e^{-\pi N^2 e^{2y}}}{1 - e^{4/N - 2\pi N e^{2y}}} \leq \frac{N^4 e^{-\pi N^2}}{1 - r_N}. \quad (\text{TR3})$$

Here $r_N = e^{4/N - 2\pi N} \in (0, 1)$: $4/N - 2\pi N \leq 4 - 2\pi < 0$ for $N \geq 1$. Multiplication by (TR2), bounding $y^J \leq L^J$ and $e^{9y/2} \leq e^{9L/2}$, and integrating over an interval of length L prove exactly

$$T_{J,N,L} = \frac{16\pi^2 L^{J+1} e^{9L/2} N^4 e^{-\pi N^2}}{1 - r_N}. \quad (\text{TR4})$$

For the omitted interval $y > L$, use (TR3) with $N = 1$, retaining its exponential numerator. This gives

$$I_J(y) \leq \frac{16\pi^2}{1 - r_1} y^J e^{9y/2 - \pi e^{2y}}, \quad r_1 = e^{4 - 2\pi}. \quad (\text{TR5})$$

For $y = L + v, v \geq 0$, the inequalities $(L + v)^J \leq L^J e^{Jv/L}$ and $e^{2(L+v)} \geq e^{2L}(1 + 2v)$ yield

$$y^J e^{9y/2 - \pi e^{2y}} \leq L^J e^{9L/2 - \pi e^{2L}} e^{-(2\pi e^{2L} - 9/2 - J/L)v}. \quad (\text{TR6})$$

Integrating when $\lambda_J(L) = 2\pi e^{2L} - 9/2 - J/L > 0$ proves exactly

$$Y_{J,L} = \frac{16\pi^2 L^J e^{9L/2 - \pi e^{2L}}}{(1 - r_1)\lambda_J(L)}. \quad (\text{TR7})$$

The first tail covers $0 \leq y \leq L, n \geq N$, and the second covers $y > L, n \geq 1$; their interiors are disjoint. The positive integrands permit Tonelli before integrability is established. The finite bounds then prove convergence and TC4.

At $N = 20, L = 4, J \leq 64$, the exact denominator signs follow already from $\pi > 3, e^8 > 41$:

$$\frac{4}{N} - 2\pi N < -\frac{599}{5}, \quad 4 - 2\pi < -2, \quad \lambda_J(4) > 246 - \frac{9}{2} - 16 = \frac{451}{2} > 0. \quad (\text{TR8})$$

Thus the quoted actual-parameter sign check is correct.

For fixed J , first choose L large enough to make $Y_{J,L}$ arbitrarily small; its double-exponential decay dominates the polynomial and exponential factors. For that fixed L , increase N to make $T_{J,N,L}$ arbitrarily small. This is a sequential choice of L , then N , not a claim that the first tail tends to zero with L while N remains fixed.

The finite integrand is entire in complex y : y^J has a nonnegative integer exponent, and all remaining operations are finite sums, products, and compositions of exponentials. There are no branch cuts, absolute values, or conjugations in the callback. Its analyticity therefore meets the recorded analytic-ball callback contract, including at $y = 0, J = 0$.

246.2 2. Recurrence, interval propagation, and finite matrix signs

The retained entire-function identity $F(z^2) = g(1/2 + iz)$, together with the even moments, gives $a_j = (-1)^j M_{2j}/(2j)!$. Extracting the coefficient of w^n from

$$F(w) \sum_{n \geq 0} b_n w^n = -F'(w)$$

gives

$$a_0 b_n + \sum_{j=1}^n a_j b_{n-j} = -(n+1)a_{n+1}, \quad (\text{TR9})$$

which is TC11. The original $a_0 = M_0 > 0$ is retained in this recurrence.

Each interval operation encloses its exact operation. Induction on n , with a positive lower bound for a_0 , therefore encloses every exact b_n . Repeated use of an interval variable can increase enclosure width, but cannot invalidate containment.

For the exact symmetric matrix, the recursion TC13 successively constructs a unit lower triangular L and diagonal D . At stage j , the formula for L_{ij} gives

$$A_{ij} = \sum_{k < j} L_{ik} D_k L_{jk} + L_{ij} D_j \quad (i > j),$$

and the pivot formula gives the same equality for $i = j$, since $L_{jj} = 1$. Symmetry supplies the other half. Thus $A = LDL^\top$. If all interval pivots have positive lower endpoints, induction proves that the exact pivots are positive and every division is defined. Hence for $v \neq 0$

$$v^* A v = \sum_j D_j |(L^\top v)_j|^2 > 0. \quad (\text{TR10})$$

The vector is nonzero after the invertible triangular map. This proves the stated positive-definiteness implication.

For a real rational vector c , let $\gamma_n = \sum_{r+s=n} c_r c_s$. Expanding the complete quadratic form gives

$$c^\top H_d c = \sum_{n=0}^{2d} \gamma_n b_n. \quad (\text{TR11})$$

This includes off-diagonal cross terms twice in the coefficient convolution when their indices differ. If $b_n \in [\ell_n, u_n]$, choosing u_n when $\gamma_n \geq 0$ and ℓ_n when $\gamma_n < 0$ maximizes that term. Therefore TC15 is a valid rational upper bound. No square-modulus form is substituted for this real bilinear form.

246.3 3. Reciprocal-zero map and the full polynomial form

The source imports the workbench's absolutely summable reciprocal-zero expansion TC16. All deductions below retain those exact multiplicities and its full infinite tail. The coordinate map in TC17 is verified directly:

$$-\frac{1}{(\delta + i\gamma)^2} = \frac{\gamma^2 - \delta^2 + 2i\gamma\delta}{(\gamma^2 + \delta^2)^2}. \quad (\text{TR12})$$

Replacing ρ by $1 - \rho$ changes $\rho - 1/2$ to its negative and leaves the square unchanged. At a zero, $\rho - 1/2 \neq 0$, because the source value $g(1/2) = M_0$ is positive. The map $w = -(\rho - 1/2)^2$ has nonzero derivative there. It preserves the local zero order, so the two reflected source zeros correspond to one zero of F of that same order. This is the exact multiplicity map used in TC16–TC17.

The finiteness of $S_* = \sum_j m_j |\beta_j|$ implies $\sup_j |\beta_j| < \infty$, since $m_j \geq 1$. Put $R_* = \max\{1, \sup_j |\beta_j|\}$. For $P(X) = \sum p_r X^r$,

$$|P(\beta_j)| \leq \sum_r |p_r| R_*^r = \|P\|_{R_*}. \quad (\text{TR13})$$

Thus $\mathcal{Q}(P) = \sum_j m_j \beta_j P(\beta_j)^2$ converges absolutely. It is real for real P because the reciprocal set and multiplicities are conjugation stable. Finite expansion of P^2 gives TC19 exactly.

For real polynomials P, E , the identity $(P + E)^2 - P^2 = 2PE + E^2$, applied termwise in that absolutely convergent series, gives

$$|\mathcal{Q}(P + E) - \mathcal{Q}(P)| \leq S_* \|E\|_{R_*} (2\|P\|_{R_*} + \|E\|_{R_*}). \quad (\text{TR14})$$

This verifies TC20 without dropping any reciprocal zero or multiplicity.

246.4 4. Separator, explicit cutoff, and all edge cases

Fix a nonreal reciprocal zero β , its conjugate, and their common multiplicity m . Let $r = |\beta|/2 > 0$. In TC21, “all other” excludes both selected points. Every element of $\mathcal{A}$ contributes at least r to S_* , so $\#\mathcal{A} \leq S_*/r$ and the set is finite. It is conjugation stable. Therefore B has real coefficients and $B(\beta) \neq 0$. The empty product is one if $\mathcal{A}$ is empty.

Either choice of c with $\beta c^2 = -1$ is nonzero. Set w_N, u_N, v_N as in TC24. They satisfy

$$u_N + v_N \beta = \Re w_N - (\Re \beta) v_N + v_N (\Re \beta + i \Im \beta) = w_N. \quad (\text{TR15})$$

Consequently $P_N(\beta) = c$, and real coefficients give $P_N(\bar{\beta}) = \bar{c}$. The two selected summands of $\mathcal{Q}(P_N)$ are each exactly $-m$. Every other reciprocal zero of modulus at least r is a root of B , so its entire weighted summand is zero, including its multiplicity.

For $|X| \leq r$, the literal product gives $|B(X)| \leq B_0$. Also

$$\begin{aligned} |u_N + v_N X| &\leq |\Re w_N| + (|\Re \beta| + r)|v_N| \\ &\leq |w_N| \left(1 + \frac{|\Re \beta| + r}{|\Im \beta|}\right). \end{aligned} \quad (\text{TR16})$$

Multiplication by $|X|^N |B(X)|$, and using $|w_N| = |c|/(|\beta|^N |B(\beta)|)$, gives

$$|P_N(X)| \leq C_* 2^{-N}. \quad (\text{TR17})$$

This includes $N = 0$, with X^0 the constant polynomial one. The full remaining reciprocal tail therefore has absolute contribution at most $C_*^2 T_* 4^{-N}$, yielding

$$\mathcal{Q}(P_N) \leq -2m + C_*^2 T_* 4^{-N}. \quad (\text{TR18})$$

If $T_* = 0$, the last term is zero for every $N \geq 0$. If $T_* > 0$, set $A = C_*^2 T_*/m > 0$ and $x = \log A / \log 4$. When $x \geq 0$, $1 + \lfloor x \rfloor > x$, so every $N \geq N_*$ satisfies $N > x$. When $x < 0$, $N \geq 0 > x$, regardless of whether the inner integer in TC23 is zero or negative. Hence in both cases

$$A 4^{-N} < 1, \quad C_*^2 T_* 4^{-N} < m. \quad (\text{TR19})$$

In particular TC23 gives the claimed weak bound $\mathcal{Q}(P_N) \leq -m$. At $A = 4^s$ with integer $s \geq 0$, the chosen cutoff is $s + 1$, not s ; the boundary case is therefore safe. The formula is conservative by one degree at that boundary, and is mathematically valid as printed.

246.5 5. Rational coefficient accuracy and interval detection

The polynomial P_N has real coefficients and degree at most $D = N + \#\mathcal{A} + 1$. Retain all $D + 1$ coefficient slots, inserting exact zeros above its actual degree if necessary. For a positive integer H , round each coefficient to a nearest element of $H^{-1}\mathbb{Z}$. Either nearest element is allowed at a tie. The error polynomial $E = \tilde{P}_N - P_N$ then has

$$|e_r| \leq \frac{1}{2H}, \quad \eta := \|E\|_{R_*} \leq \frac{\sum_{r=0}^D R_*^r}{2H}. \quad (\text{TR20})$$

Every denominator in TC25 is positive: $m > 0$, $S_* > 0$ because it includes the selected pair, and $2\|P_N\|_{R_*} + 1 > 0$. The finite geometric sum is positive. Thus a sufficiently large positive integer H always satisfies TC25.

The two bounds in TC25 give $\eta \leq 1$ and $\eta \leq m/[2S_*(2\|P_N\|_{R_*} + 1)]$. By (TR14),

$$\begin{aligned} |\mathcal{Q}(\tilde{P}_N) - \mathcal{Q}(P_N)| &\leq S_* \eta (2\|P_N\|_{R_*} + \eta) \\ &\leq S_* \eta (2\|P_N\|_{R_*} + 1) \leq m/2. \end{aligned} \quad (\text{TR21})$$

Together with (TR18)–(TR19), this proves $\mathcal{Q}(\tilde{P}_N) \leq -m/2 < 0$. The error estimate includes a coefficient that rounds from a nonzero value to zero; such rounding is permitted and does not invalidate the proof.

For clarity, the eventual finite-interval claim has a direct quantitative margin. Write c for the rational coefficient vector of $\tilde{P}_N$, define γ_n as in (TR11), and set $A_c = \sum_n |\gamma_n|$. The polynomial is nonzero because its form is negative, so its square is nonzero and $A_c > 0$. If rational enclosing intervals for every required b_n have width at most $m/(4A_c)$, then their signed upper bound satisfies

$$U(c) - \mathcal{Q}(\tilde{P}_N) \leq \sum_n |\gamma_n| (u_n - \ell_n) \leq m/4, \quad U(c) \leq -m/4 < 0. \quad (\text{TR22})$$

This proves an explicit sufficient finite enclosure width. There is no need to assume cancellation or independent errors.

For finitely many required coefficients, shrinking the moment intervals shrinks the resulting b_n intervals: TC11 uses finitely many additions, products, and reciprocals, and one can first restrict the a_0 interval to have lower endpoint at least $M_0/2 > 0$. Every such interval operation is continuous at those exact inputs; induction in n proves convergence of enclosure widths to zero. The positive tail bounds can be made arbitrarily small by the sequential choice of L, N established above.

The finite integral itself admits arbitrarily small validated errors. One direct existence proof uses the entire finite integrand f on $[0, L]$. On all unit complex discs about that interval, a finite bound for $|f|$ is

$$K = (L + 2)^J e^{(L+1)/2} \sum_{n=1}^{N-1} \left(16\pi^2 n^4 e^{4(L+1)} + 24\pi n^2 e^{2(L+1)} \right) e^{\pi n^2 e^{2(L+1)}}. \quad (\text{TR23})$$

Indeed $\Re y \leq L + 1$, $|y| \leq L + 2$, and $|e^{-\pi n^2 e^{2y}}| \leq e^{\pi n^2 e^{2\Re y}}$. Cauchy's derivative estimate on each unit circle gives $|f'(x)| \leq K$ for $x \in [0, L]$. Composite midpoint quadrature on a uniform mesh of width $h = L/s$ has error at most $KLh/4$, by integrating $K|x - x_{\text{mid}}|$ on each interval. Finite evaluations of the explicit exponential expression can be enclosed to arbitrary accuracy; outward rational bounds for K suffice. If $N = 1$, the finite integrand is zero and this step is immediate. This proves the finite integration approximation needed for (TR22), independently of any fixed evaluation limit of the particular integration run.

246.6 6. Relation to the recorded finite certificate

For dimension 16, $d = 15$. The unshifted matrix uses $b_0, \dots, b_{30}$, and the shifted one uses $b_1, \dots, b_{31}$. TC11 computes these from $a_0, \dots, a_{32}$, hence exactly the stated 33 even moments $M_0, M_2, \dots, M_{64}$. The index ranges are consistent. Positivity of both sets of sixteen exact pivots proves TC27 by (TR10); every smaller leading matrix is positive definite by restriction of the same positive quadratic form.

The parent performs the complete rational endpoint and replay audit. This subreview supplies the independent mathematical derivation and does not turn a finite-dimensional sign result into a claim at larger dimensions. Likewise the separator theorem constructs and bounds the witness associated with each specified nonreal reciprocal zero; it asserts no universal cutoff and supplies no nonreal zero of the actual zeta function.

247 Root acceptance of the original theta certificate and complete proof closure

13 September 2026. This is the final local mathematical and execution review for the current finite certificate. It does not close the wider Split-Zero/RH research goal.

247.1 Exact accepted calculation

Both original real symmetric matrices

$$H_{15} = (b_{i+j})_{0 \leq i,j \leq 15}, \quad H_{15}^{(1)} = (b_{i+j+1})_{0 \leq i,j \leq 15}$$

are positive definite. The coefficients are those of the actual $-F'/F$, with $F(z^2) = 2\xi(1/2 + iz)$. All 33 moments $M_0, M_2, \dots, M_{64}$ are calculated from the original theta integral. All 32 pivots and all 32 leading determinants have positive rigorous lower endpoints. The original mass and all monomial coordinates remain unchanged.

The complete integrator, CH.1–19 method proof, TR1–33 analytic/code review, and TC1–28 root proof have been read. The two omitted regions are disjoint, their integrands are nonnegative, and their upper bounds retain the factor $16\pi^2$, the original exponential factors and both exact denominators. The complex integration callback is entire. Its real ball contains the real integral; the positive tail interval is added with outward rounding. The dyadic exporter uses exact outward lower/upper endpoints and their integer mantissa/exponent, with no decimal conversion in the certificate.

247.2 Independent integer arithmetic and actual replay

The saved independent script `theta_certified_hankel_exact_rational_review_20260913.py` was read completely. It imports no flint or floating-point arithmetic. It uses a fixed grid $Q = 2^{4096}$: an interval is the exact pair $[\ell/Q, u/Q]$ of integers. Addition and negation are exact; multiplication takes the minimum and maximum of all four integer endpoint products and rounds outward after division by Q . Squaring uses zero as its lower endpoint when the interval crosses zero. For a positive interval its reciprocal is enclosed by

$$\left[\frac{\lfloor Q^2/u \rfloor}{Q}, \frac{\lceil Q^2/\ell \rceil}{Q} \right].$$

Negative reciprocals are obtained by the exact negation map. These formulas prove containment of every operation, including all rounded operations.

The script reconstructs each moment from the eight exported finite-piece intervals and the sum of the two exported tail upper bounds. It does not use the saved moment, coefficient or pivot values to calculate its result. It then propagates the original factorial/sign formula and logarithmic recurrence and independently performs both unscaled LDL recursions. Every denominator is checked positive before division. The complete matrix identity and positive-definiteness proof are TC13 and CH.15–17.

Root ran a fresh validated integration after the independent review worker hit its usage limit. The fresh certificate is `reviewer_replay_dimension16_1024.json`, SHA-256 `0fcac21e20680a6d6a3fab1671b0782b56de005ce749ee33373b1193f20a0af7`. The complete numerical payload agrees exactly with the original certificate; elapsed time and platform fields are excluded from that comparison. Root then executed the independent integer script successfully in ordinary Python. It validated 1,400 exact intervals, reconstructed both matrix certificates, and proved all 32 positive pivots and determinants. It also proved by exact rational comparison that the readable TC28 interval contains the full exported determinant interval.

The original certificate SHA-256 is `869ebacd3f82e46c3fe5fac1f07bcbaae7f4c333e1a5ba2e0ffc b1f91884a0fc`. The reviewed integrator SHA-256 is `a97486edc2fc1f05f155a9539ad280433be39a`

8f6924efbc8c1c1c4d71033950. The independent integer script SHA-256 is a181ef220578eaf232b3e01398d61b1a6f36625f056c5e6bd365453b9ebfa885. Its successful complete rational output is supplied alongside this proof. The script uses Python assertions for validation and must be run without the optimization switch. No optimized-mode verifier claim is made.

247.3 Written-proof corrections and closure

The complete TC mathematical subreview accepted every displayed bound and reported two prose clarifications: coefficient rounding must mean a nearest multiple, with either tie choice allowed; every coefficient slot enters the error bound even when a nonzero coefficient rounds to zero. Both are now explicit in the accepted source. Its current SHA-256 is 8dab2193a7ef3287f58ff5038fc34988883d8899dc4a2a9868098856b48772a5. The earlier subreview remains a record of the reviewed predecessor and its resolved findings. The bounds and their indices were unchanged.

The complete workbench NOTE.tex and WBR1–41 independent proof were read. The archived separator defines u_N and then writes ν_N in its boxed formula. The exact correction is the identity $\nu_N := u_N$; the archive is preserved and the consistent full formula appears in WBR16 and TC24. The rational functional calculus has the exact full local inverse WBR29, and its two reflected modules remain separate through WBR33. The half-trace, nilradical and critical-observation defect are completely proved in WBR34–40.

The workbench originally invokes the classical genus-zero factorization without including its proof. The additional complete source tau_genus_zero_product_proof_20260913.tex, GF1–13, now proves the precise case used. Root wrote and read back that whole proof. It derives the circle-mean zero formula, the $O(r^\alpha)$ zero count, absolute reciprocal summability, uniform product convergence, a lower bound for the product on explicitly selected zero-avoiding circles, and constancy of the entire zero-free factor from its Fourier coefficients. It then derives the full logarithmic-derivative expansion. Taking $\alpha = 3/4$ applies it to WBR9's explicit theta growth bound. Its SHA-256 is 9bade2c098f1b03ba4ec4e526f4dffe4ced36f70bd7a533931a16335b162c394. This is an included proof of a classical theorem, not a novelty claim. It is root-reviewed; no separate independent acceptance of GF is claimed.

The finite dimension-16 certificate does not require factorization or any assumed zero location. Factorization belongs to the separate proof that positivity of the original unshifted matrices in every dimension is equivalent to RH. The complete finite tails and rational rounding formula give rigorous finite witnesses without choosing a replacement metric. The actual computation produced positive finite matrices and no negative witness. It proves no sign statement at larger dimensions.

248 Independent final review: the full genus-zero proof and the positive theta tails

Date: 2026-09-13.

The complete files `tau_genus_zero_product_proof_20260913.tex` (GF1–GF13) and `theta_certified_tail_subreview_20260913.md` (TT1–TT12) were read and checked. The original workbench `NOTE.tex` was also read in full to check the exact function, coefficient convention, and invocation of the product theorem. A separate reviewer read the entire retained `certify_theta_hankel.py` and matched its callback and tail expressions to TT1–TT12. No source file was modified and no integration, Lean run, or remote publication was performed in this review.

Acceptance: GF1–GF13 and TT1–TT12 are mathematically valid with their original constants, signs, multiplicities, and domains. No correction is required. The explicit derivation below supplies the original-theta growth estimate invoked in the first paragraph of GF, and the remainder checks every step of the product argument and of the two tail estimates. The finite computation’s exact arithmetic and numerical integration certification are outside this review; accepting the tail formulas does not by itself certify those separate operations.

248.1 1. Exact sources and the original analytic input

The reviewed bytes are:

The original source in the workbench is

$$\phi_*(x) = (4\pi^2 x^4 - 6\pi x^2)e^{-\pi x^2}, \quad f_0(x) = 2 \sum_{n \geq 1} \phi_*(nx), \quad \psi(y) = e^{y/2} f_0(e^y). \quad (\text{GFR1})$$

The supplied Mellin identity and reflection give

$$g(1/2 + iz) = \int_{\mathbb{R}} \psi(y) e^{izy} dy, \quad \psi(-y) = \psi(y), \quad g = 2\xi. \quad (\text{GFR2})$$

The workbench’s coefficients specify the entire function by

$$F(w) = \sum_{j \geq 0} \frac{(-1)^j M_{2j}}{(2j)!} w^j, \quad M_{2j} = \int_{\mathbb{R}} y^{2j} \psi(y) dy, \quad F(z^2) = g(1/2 + iz). \quad (\text{GFR3})$$

All factors of two in (GFR1)–(GFR3) are retained. In particular, the original value is $F(0) = g(1/2) = \int_{\mathbb{R}} \psi(y) dy > 0$.

Here is a completely explicit route from the source to GF1. Put

$$\rho = \exp(4 - 2\pi), \quad C_\theta = \frac{8\pi^2}{1 - \rho}. \quad (\text{GFR4})$$

Because $\pi > 3, 0 < \rho < 1$. For $n \geq 1$,

$$\frac{(n+1)^4 e^{-\pi((n+1)^2-1)}}{n^4 e^{-\pi(n^2-1)}} = (1+1/n)^4 e^{-\pi(2n+1)} \leq e^{4/n-2\pi n} \leq \rho.$$

The first term of the sequence is one, so its sum is at most $(1-\rho)^{-1}$. For $y \geq 0$, the literal summand of ψ is positive and bounded above by its positive fourth-power term. Consequently

$$\begin{aligned} 0 < \psi(y) &\leq 8\pi^2 e^{9y/2-\pi e^{2y}} \sum_{n \geq 1} n^4 e^{-\pi(n^2-1)e^{2y}} \\ &\leq C_\theta e^{9y/2-\pi e^{2y}}. \end{aligned} \tag{GFR5}$$

Reflection gives the same estimate with $|y|$. For every fixed $s \geq 0$, this bound times $e^{s|y|}$ is integrable. It justifies the power-series expansion and differentiations in (GFR2) by domination on every compact set of z . The evenness of ψ removes exactly the odd coefficients. It also proves convergence of (GFR3) on every compact set of w , since one can compare the absolute series with the even exponential series at $|z| = \sqrt{|w|}$.

For $R \geq 1$ and every $|w| \leq R$, choose one number z with $z^2 = w$. This pointwise choice uses no holomorphic square-root branch; it only gives $|z| \leq \sqrt{R}$. Let $a = 9/4 + \sqrt{R}/2$. Equation (GFR5) gives

$$\begin{aligned} |F(w)| &\leq 2C_\theta \int_0^\infty e^{(9/2+\sqrt{R})y-\pi e^{2y}} dy \\ &= C_\theta \int_1^\infty t^{a-1} e^{-\pi t} dt \leq C_\theta \pi^{-a} \Gamma(a). \end{aligned} \tag{GFR6}$$

The substitution is exactly $t = e^{2y}$, so $dy = dt/(2t)$. The factor two from the two half-lines cancels this denominator two. For $a > 1$, the positive function $t^{a-1}e^{-t/2}$ has its maximum at $t = 2(a-1)$; this follows from its logarithmic derivative $(a-1)/t - 1/2$. Thus

$$\Gamma(a) = \int_0^\infty (t^{a-1} e^{-t/2}) e^{-t/2} dt \leq 2 \left(\frac{2(a-1)}{e} \right)^{a-1}. \tag{GFR7}$$

Write $K_0 = \max\{0, \log(2C_\theta)\}$. Since $a-1 = 5/4 + \sqrt{R}/2 \leq 7\sqrt{R}/4$, equations (GFR6)–(GFR7) imply

$$\log M_F(R) \leq K_0 + \frac{7}{4}\sqrt{R} \log \frac{7}{2} + \frac{7}{8}\sqrt{R} \log R. \tag{GFR8}$$

In deriving this upper bound, the terms $-(a-1) - a \log \pi$ were discarded only because they are negative; the original function and its mass remain unchanged. For $R \geq 1$, $\log R/R^{1/4} \leq 4/e$: putting $u = \log R \geq 0$, the derivative of $ue^{-u/4}$ is $e^{-u/4}(1-u/4)$, whose maximum value is $4/e$. Hence a concrete choice in GF1 is

$$\alpha = \frac{3}{4}, \quad R_0 = 1, \quad C = K_0 + \frac{7}{4} \log \frac{7}{2} + \frac{7}{2e} > 0. \tag{GFR9}$$

This derivation proves the growth hypothesis for precisely the original F . It does not use zero ordinates, a product formula, or an assumed location of zeros.

248.2 2. Counting all zeros, with their multiplicities

For the general entire function in GF1, $F(0) \neq 0$ ensures that the function is not identically zero and that all zeros have positive modulus. Zeros in any compact disk are finite, counting multiplicities. Choose a radius R whose circle has no zero and divide F by the factors $z - a_j$ for all its zeros in that disk. The quotient extends holomorphically through those zeros and is nonvanishing on a slightly larger disk: the boundary circle is compact and nonvanishing, so an annular neighborhood of it contains no zero. Its logarithmic derivative has a primitive on this disk, obtained from its power series. If L' is that logarithmic derivative, differentiating the quotient times e^{-L} gives zero, so this quotient equals a nonzero constant times e^L . A choice of a complex logarithm of the constant supplies its holomorphic logarithm.

The mean of the real part of a holomorphic logarithm equals its central value by its uniformly convergent Taylor series on the circle. For a removed zero $|a_j| < R$, the uniformly convergent expansion

$$\log(1 - a_j e^{-i\theta}/R) = - \sum_{k \geq 1} \frac{(a_j/R)^k e^{-ik\theta}}{k}$$

has real part of mean zero. Thus the mean of $\log |R e^{i\theta} - a_j|$ is exactly $\log R$. Subtracting the central value of the removed linear factors gives GF3, including the term $\log |F(0)|$ and each repeated zero.

For sufficiently large r , the set of excluded radii in $(2r, 3r)$ is finite. Choose any other R there. Every zero with $|a_j| \leq r$ contributes at least $\log 2$, whereas every other term in GF3 is nonnegative. Therefore

$$n(r) \log 2 \leq C(3r)^\alpha - \log |F(0)|. \quad (\text{GFR10})$$

This proves $n(r) \leq C_1 r^\alpha$ for all sufficiently large r . Choose $r_0 > 0$ strictly below the modulus of every zero. Such a radius exists by nonvanishing at zero; if the zero set is empty any positive radius works. On the remaining bounded interval, $n(r)/r^\alpha$ is bounded above by a fixed finite count divided by r_0^α . Enlarging C_1 therefore proves the estimate for every $r \geq r_0$.

Partition the zeros into the half-open annuli $2^k r_0 < |a_j| \leq 2^{k+1} r_0$, $k \geq 0$. There are no zeros omitted below or at r_0 . Each term in the k -th annulus is at most $(2^k r_0)^{-1}$, and that annulus contains at most $n(2^{k+1} r_0)$ zeros. Consequently

$$\sum_j |a_j|^{-1} \leq C_1 2^\alpha r_0^{\alpha-1} \sum_{k \geq 0} 2^{k(\alpha-1)} < \infty. \quad (\text{GFR11})$$

This verifies GF4 without a density assumption and with every multiplicity included.

248.3 3. Construction of the literal product and the selected-circle bound

Let $P(z) = \prod_j (1 - z/a_j)$. For a fixed disk $|z| \leq A$, only finitely many zeros have modulus at most $2A$. For every remaining factor, the power-series logarithm obeys

$$|\log(1 - z/a_j)| \leq \sum_{k \geq 1} |z/a_j|^k / k \leq \frac{|z/a_j|}{1 - |z/a_j|} \leq 2A/|a_j|. \quad (\text{GFR12})$$

By (GFR11) these logarithms have an absolutely and uniformly convergent sum. Its exponential has no zero on the disk. Multiplication by the preceding finite factors therefore gives a holomorphic function with exactly the prescribed zeros and orders there. The constructions agree on intersections because they use the same absolutely convergent tail and finite factors. They define the entire P , independent of the enumeration of zeros, with $P(0) = 1$.

At each zero, F and P have the same order and a nonzero leading coefficient, so $H = F/P$ extends as a nonvanishing holomorphic function. Thus H is nonvanishing entire. Integrating the entire power series of H'/H and choosing the constant at zero gives an entire h satisfying $H = e^h$. No bound on $1/P$ has been used in this construction.

For sufficiently large t , set $N_t = n(4t)$ and $\delta_t = t/[4(N_t + 1)]$. The union of the open intervals of radius δ_t about the at most N_t zero moduli at most $4t$ has total length at most $2N_t\delta_t = tN_t/[2(N_t + 1)] < t/2$. The interval $[t, 2t]$ has length t , so a radius R_t outside the union exists. For every $|z| = R_t$ and every zero $|a_j| \leq 4t$, the reverse triangle inequality yields

$$|1 - z/a_j| = \frac{|a_j - z|}{|a_j|} \geq \frac{|R_t - |a_j||}{4t} \geq \frac{1}{16(N_t + 1)}. \quad (\text{GFR13})$$

Repeated zeros merely repeat factors; counting their excluded intervals more than once only weakens the estimate on the union length. For every remaining zero, $|a_j| > 4t$ and $|z| \leq 2t$, so $|z/a_j| < 1/2$. Equation (GFR12) implies $\log |1 - z/a_j| \geq -2|z|/|a_j|$. Using annuli $2^k 4t < |a_j| \leq 2^{k+1} 4t$, exactly the counting argument above gives

$$\sum_{|a_j| > 4t} |a_j|^{-1} \leq \frac{C_1 2^\alpha 4^{\alpha-1}}{1 - 2^{\alpha-1}} t^{\alpha-1} = C_2 t^{\alpha-1}. \quad (\text{GFR14})$$

Both the finite log sum and its uniformly convergent infinite tail can now be evaluated on the full circle, giving

$$\log |P(z)| \geq -N_t \log(16(N_t + 1)) - 2R_t C_2 t^{\alpha-1}. \quad (\text{GFR15})$$

For completeness, put $A = C_1 4^\alpha$. For $t \geq e$, $N_t \leq At^\alpha$, $N_t + 1 \leq (A + 1)t^\alpha$, and $R_t \leq 2t$. Thus

$$\begin{aligned} N_t \log(16(N_t + 1)) &\leq At^\alpha [\log(16(A + 1)) + \alpha \log t], \\ 2R_t C_2 t^{\alpha-1} &\leq 4C_2 t^\alpha. \end{aligned}$$

Taking $C_3 = A[\log(16(A + 1)) + \alpha] + 4C_2$ proves GF9 for all these sufficiently large t . The proof covers infinitely many, finitely many, or no zeros; an empty finite log sum contributes zero.

248.4 4. The exact argument forcing the zero-free quotient to be constant

On the selected circle, F and P are nonzero. Therefore $\Re h = \log |H| = \log |F| - \log |P|$. For large t , GF1 applies at R_t and yields

$$\Re h(z) \leq C 2^\alpha t^\alpha + C_3 t^\alpha \log t \leq B_t := (C 2^\alpha + C_3) t^\alpha \log t \quad (|z| = R_t), \quad (\text{GFR16})$$

where $t \geq e$. The product $C 2^\alpha$ retains the original growth constant C ; the tail constant C_2 has already entered through C_3 .

Write $h(z) = \sum_{k \geq 0} d_k z^k$. On any fixed circle this series and its conjugate converge uniformly. For every integer $\ell \geq 1$, multiplying

$$\Re h(R_t e^{i\theta}) = \frac{1}{2} \sum_{k \geq 0} d_k R_t^k e^{ik\theta} + \frac{1}{2} \sum_{k \geq 0} \overline{d_k} R_t^k e^{-ik\theta}$$

by $e^{-i\ell\theta}$ and integrating gives exactly

$$\frac{1}{\pi} \int_0^{2\pi} \Re h(R_t e^{i\theta}) e^{-i\ell\theta} d\theta = d_\ell R_t^\ell. \quad (\text{GFR17})$$

Only the first sum's term $k = \ell$ survives. In particular, the coefficient $1/\pi$ in GF10 is correct. The integral of the constant B_t times $e^{-i\ell\theta}$ is zero. Since $B_t - \Re h \geq 0$, the triangle inequality and the mean-value identity give

$$|d_\ell| R_t^\ell \leq \frac{1}{\pi} \int_0^{2\pi} (B_t - \Re h(R_t e^{i\theta})) d\theta = 2(B_t - \Re h(0)). \quad (\text{GFR18})$$

For fixed $\ell \geq 1$, divide by $R_t^\ell \geq t^\ell$. The upper bound tends to zero because $t^{\alpha-\ell} \log t \rightarrow 0$ and $\alpha < 1 \leq \ell$. Hence $d_\ell = 0$ for every positive ℓ . This proves that h , and therefore H , is constant. Its value is determined without modifying the original source: $H(0) = F(0)/P(0) = F(0)$. The result is the literal factorization

$$F(z) = F(0) \prod_j (1 - z/a_j). \quad (\text{GFR19})$$

This proof does not invoke the conclusion of a factorization theorem as an input. The counting, convergence, selected-circle lower bound, and Fourier-coefficient bound together prove the entire special case used by the workbench.

248.5 5. The logarithmic coefficient map retains every multiplicity

Group repeated zeros and put $\beta_j = 1/a_j$, now indexing distinct zeros with multiplicities m_j . Equation (GFR11) gives $S = \sum_j m_j |\beta_j| < \infty$, and the β_j are bounded because there is a zero-free neighborhood of zero. Choose $r > 0$ with $r|\beta_j| \leq 1/2$ for all j ; if there are no zeros any positive r works. For $|z| \leq r$,

$$\sum_j \left| \frac{m_j \beta_j}{1 - \beta_j z} \right| \leq 2S. \quad (\text{GFR20})$$

The uniform logarithm convergence used to construct P , together with this uniform derivative bound, permits termwise differentiation there. Equivalently, integrate this uniformly convergent derivative series from zero and compare the analytic logarithms, whose values at zero are fixed. In either construction,

$$-\frac{F'(z)}{F(z)} = \sum_j \frac{m_j \beta_j}{1 - \beta_j z}.$$

The double geometric series is absolutely summable because

$$\sum_j \sum_{n \geq 0} m_j |\beta_j|^{n+1} r^n = \sum_j \frac{m_j |\beta_j|}{1 - r|\beta_j|} \leq 2S. \quad (\text{GFR21})$$

Thus its sums can be interchanged, and the coefficient of z^n is exactly $\sum_j m_j \beta_j^{n+1}$. This proves GF13 and the workbench's logarithmic coefficients in their original scalar coordinate. It leaves the reflected packet modules, their nilpotents, and their independent operator constructions unchanged upstream of that scalar map.

248.6 6. Verification of the positive tails and the exact omitted regions

For the half-line moment integrand define, exactly as in TT1,

$$x_n(y) = \pi n^2 e^{2y}, \quad f_{J,n}(y) = y^J e^{y/2} (16x_n(y)^2 - 24x_n(y)) e^{-x_n(y)}. \quad (\text{GFR22})$$

Here $y \geq 0$, $n \geq 1$, and J is a nonnegative integer. At $J = 0$, y^J is the constant polynomial one. For even J , summing and integrating (GFR22) is precisely M_J in (GFR3): the source factor two and the reflection factor two are both already present in the coefficients 16 and -24 .

Because $x_n(y) \geq \pi > 3/2$, $16x_n^2 - 24x_n = 8x_n(2x_n - 3) > 0$. Therefore

$$0 \leq f_{J,n}(y) \leq 16\pi^2 n^4 y^J e^{9y/2 - \pi n^2 e^{2y}}. \quad (\text{GFR23})$$

The finite callback keeps $1 \leq n < N$ on $[0, L]$. Up to their measure-zero common boundary, the omitted regions are exactly $n \geq N$, $0 \leq y \leq L$ and $n \geq 1$, $y \geq L$. They are disjoint and their union is the full complement of the retained region. Positivity permits the sum and integral interchanges by Tonelli's theorem; the bounds below prove their total finiteness.

On $[0, L]$, the majorant in (GFR23) is at most $16\pi^2 n^4 L^J e^{9L/2 - \pi n^2}$. Integrating the interval of length L and setting $a_n = n^4 e^{-\pi n^2}$ gives the upper bound $16\pi^2 L^{J+1} e^{9L/2} \sum_{n \geq N} a_n$. For every $n \geq N$,

$$\frac{a_{n+1}}{a_n} = (1 + 1/n)^4 e^{-\pi(2n+1)} \leq e^{4/n - \pi(2n+1)} \leq e^{4/N - 2\pi N} =: \rho_n. \quad (\text{GFR24})$$

The final symbol is constant for the selected first omitted index N ; its subscript does not introduce a summation over ratios. For $\rho_n < 1$, induction and the geometric sum give the full upper bound

$$T_n = \frac{16\pi^2 L^{J+1} e^{9L/2} N^4 e^{-\pi N^2}}{1 - e^{4/N - 2\pi N}}. \quad (\text{GFR25})$$

For the omitted y -interval, apply the same exact ratio at fixed $y \geq 0$:

$$\frac{(n+1)^4 e^{-\pi(n+1)^2 e^{2y}}}{n^4 e^{-\pi n^2 e^{2y}}} \leq e^{4/n - 2\pi n e^{2y}} \leq e^{4 - 2\pi e^{2y}} \leq \rho_y := e^{4 - 2\pi} < 1. \quad (\text{GFR26})$$

The first term is $e^{-\pi e^{2y}}$; hence the full n -sum in (GFR23) is bounded by it divided by $1 - \rho_y$. Put $V_J(y) = y^J e^{9y/2 - \pi e^{2y}}$, which is positive on $[L, \infty)$ when $L > 0$. Its logarithmic derivative is

$$\frac{V'_J(y)}{V_J(y)} = \frac{J}{y} + \frac{9}{2} - 2\pi e^{2y} \leq \frac{J}{L} + \frac{9}{2} - 2\pi e^{2L} = -\delta, \quad \delta = 2\pi e^{2L} - \frac{9}{2} - \frac{J}{L}. \quad (\text{GFR27})$$

When $\delta > 0$, integration from L to y gives $V_J(y) \leq V_J(L) e^{-\delta(y-L)}$. Its integral is at most $V_J(L)/\delta$. Thus the second omitted region is bounded above by

$$T_y = \frac{16\pi^2 L^J e^{9L/2 - \pi e^{2L}}}{(1 - e^{4 - 2\pi})(2\pi e^{2L} - 9/2 - J/L)}. \quad (\text{GFR28})$$

These are exactly TT6 and TT10. At the actual parameters $N = 20$, $L = 4$, $0 \leq J \leq 64$, the elementary bounds $\pi > 3$ and $e^8 > 1 + 8 = 9$ give

$$4/N - 2\pi N < -599/5, \quad 4 - 2\pi < -2, \quad \delta > 54 - 9/2 - 16 = 67/2 > 0. \quad (\text{GFR29})$$

All denominators are strictly positive. Consequently the literal omitted integral belongs to $[0, T_n + T_y]$. The negative summand $-24x_n$ remains part of the exact integral and finite callback; its removal in (GFR23) is solely the proved inequality bounding the omitted tails.

248.7 7. Analytic callback and source-to-proof comparison

The retained callback extends to every complex y as

$$y^J e^{y/2} \sum_{n=1}^{N-1} (16\pi^2 n^4 e^{4y} - 24\pi n^2 e^{2y}) e^{-\pi n^2 e^{2y}}. \quad (\text{GFR30})$$

It is a finite sum of products and compositions of entire functions, and y^J is a polynomial. Thus it is entire, including at zero for every allowed J . It has no branch choice or hidden singularity. Treating π as its exact real constant, or any fixed constant value in an enclosing ball, does not alter this analyticity statement. The callback's complex ball value must enclose the exact expression; a possibly wide or nonfinite enclosure is a numerical issue, not an analytic singularity. The retained caller separately rejects a nonfinite integration result.

The separate full code comparison verified the following literal correspondence: the callback loops through $n = 1, \dots, N - 1$; tn is (GFR25); ty and decay are (GFR28) and (GFR27); the default values are $N = 20, L = 4$; dimension 16 requests exactly $J = 0, 2, \dots, 64$; the retained integral is partitioned into the eight half-unit intervals with endpoints $j/2, (j+1)/2, 0 \leq j \leq 7$. The denominator comparisons must succeed before the code proceeds. The code forms `arb(0).union((tn+ty).upper())`, which encloses the proved interval $[0, T_n + T_y]$ whenever the computed balls enclose the stated expressions. Ignoring the callback's analytic flag is consistent with the entire formula (GFR30). This establishes the exact code-to-tail-formula match without asserting an integration replay.

248.8 8. Acceptance and scope

Every numbered mathematical step GF1–GF13 and TT1–TT12 is accepted. The original-theta specialization of GF1 has the explicit constants in (GFR4) and (GFR9), and its product and logarithmic coefficients follow from the complete proof above. The original half-line tail formulas have the exact constants and denominator signs in (GFR25)–(GFR29). No alteration of the original input, source mass, coefficient coordinate, multiplicity, finite integration interval, or first omitted index is needed.

This review establishes these analytic statements and their exact callback correspondence. It makes no claim that a finite collection of positive Hankel matrices proves RH or that the broader absolute-base geometric program fails. Those conclusions do not follow from the statements proved here.

249 SplitZero: maps, support fibres, ideals, and exact corrections

12 September 2026. The construction and existing manuscript results are attributed to the owner's research programme. This note gives proofs for the bounded structural package; it does not assert global priority or a completed analytic programme. Validation is tied to exact source hashes in `VALIDATION.json`.

249.1 Conventions

For a commutative ring R , write $G(R)$ for a supported copy of R together with one extra point τ . Supported elements add and multiply as in R . The point τ is the additive identity and multiplicative absorber. Write e for supported 0_R . Thus e is not τ , $e+e=e$, $e*r=e$ for every supported r , and $1+e=1$. None of the following statements requires R to be nontrivial.

249.2 1. Exact universal morphisms

Let $p:G(R) \rightarrow R$ send τ to 0 and supported r to r . Composition with p gives a bijection

$$\text{Hom_ring}(R,A) \cong \text{Hom_semiring}(G(R),A)$$

for every commutative ring A . Indeed, for a semiring homomorphism h , the equation $e+e=e$ implies $h(e)+h(e)=h(e)$, hence $h(e)=0$ by cancellation. Therefore $r \mapsto h(r)$ is a unital ring map and factors h through p . Uniqueness follows from surjectivity of p . In particular, no semiring map $G(R) \rightarrow A$ to a ring is injective: it identifies e and τ .

Let B be the Boolean semiring. The support character $\text{chi}:G(R) \rightarrow B$ sends τ to 0 and every supported r to 1 . It is unique: $e=1+(-1)$ gives $h(e)=1$ for every unital semiring map h to B ; then $re=e$ gives $h(r)=1$. The map $(p,\text{chi}):G(R) \rightarrow R \times B$ is injective with image exactly $\{(0,0)\} \cup (R \times \{1\})$. The second coordinate distinguishes absence from a supported zero; the first distinguishes supported amplitudes.

Every ring map $f:R \rightarrow S$ lifts to $G(f)$, fixing τ and acting by f on supported elements. Conversely, if $H:G(R) \rightarrow G(S)$ is a semiring map, $p_S \circ H$ factors through p_R as a unique ring map f . The support coordinate of H equals chi_R by uniqueness of the Boolean character. Thus H and $G(f)$ have equal amplitude and support and are equal by joint injectivity. Consequently

$$\text{Hom_semiring}(G(R),G(S)) \cong \text{Hom_ring}(R,S).$$

This identifies the morphisms without asserting $G(R) \cong R$. In Lean the exact statements are `ringHomEquiv`, `coordinates_injective`, `coordinates_image`, and `splitHomEquiv`.

249.3 2. Intrinsic support and fibre modules

For any $G(R)$ -semimodule M , put $s(m)=e*m$. The scalar identities imply

$$s(m+n)=s(m)+s(n), s(s(m))=s(m), m+s(m)=m, s(m)+s(m)=s(m).$$

Conversely suppose $y+y=y$. Put $v=(-1_R)*y$. Since $e=1_R+(-1_R)$, $s(y)=y+v$. Therefore $y+s(y)=(y+y)+v=y+v=s(y)$, while absorption gives $y+s(y)=y$. Hence $s(y)=y$. Thus the support set $L=\{l:s(l)=l\}$ is exactly the additive-idempotent locus. Addition gives its join, $l \leq k$ iff $l+k=k$, and its least element is 0_M .

For $l \in L$, define $M_l=\{m:s(m)=l\}$. This is an actual R -module: addition is inherited, its zero is l , inverse is $m \mapsto (-1_R)*m$, and r acts as supported r . The essential identities are

$$s(m+n)=l+l=l, m+l=m, m+(-1_R)m=l, er=e.$$

For $l \leq k$, $T_{lk}(m)=m+k$ lies in M_k . It is additive because $k+k=k$. Every supported scalar fixes k , since $rk=r(ek)=(re)k=ek=k$; hence T_{lk} is R -linear. Also $T_{ll}=\text{id}$ and $T_{kn}T_{lk}=T_{ln}$ by absorption and $k+n=n$.

A $G(R)$ -linear map F commutes with s . Its support restriction preserves zero and joins by $F(0)=0$ and $F(l+k)=F(l)+F(k)$; its fibre restriction is R -linear. Naturality is the literal equation $F(m+k)=F(m)+F(k)$. Lean implements the fibre restrictions as `LinearMaps` and checks transport identity, composition and this naturality square.

Finally $m \mapsto (s(m), m)$ is a bijection with the disjoint union of the intrinsic fibres. If $u=s(m)+s(n)=s(m+n)$, the reconstructed sum is

$$(m+u)+(n+u)=m+n+u=m+n.$$

The Lean package supplies the forward fibre construction and reconstruction for an existing semimodule. It does not yet construct the semimodule associated with every arbitrary abstract diagram or the complete categorical equivalence with natural isomorphisms. These are separate remaining implementation steps; the manuscript already proves the equivalence on paper.

249.4 3. Complete ideal classification

For $I \triangleleft R$ let $I^G = p^{(-1)}(I) = I \cup \{\tau\}$. This contains e , so it is not the zero semiring ideal $\{\tau\}$. Conversely, if $J \triangleleft G(R)$ differs from $\{\tau\}$, choose a supported $r \in J$. Multiplication by e gives $e \in J$. Therefore $J \cap R$ contains 0_R and is closed under addition and multiplication by arbitrary R -elements, hence is a ring ideal. The two constructions are mutually inverse and preserve inclusion. Thus

$$\text{Ideal}(R) \cong \{J \in \text{Ideal}(G(R)) : J \neq \{\tau\}\}$$

as ordered sets. Equivalently every J is either $\{\tau\}$ or uniquely I^G . The whole ideal poset has one additional bottom element below $(0_R)^G = \{\tau, e\}$. Lean constructs `nonzeroIdealOrderIso`, not merely a conditional theorem assuming the classification.

249.4.1 Empty joins

The isomorphism preserves joins computed in the non-bottom ideal poset. In the ambient $\text{Ideal}(G(R))$, however, the empty join is $\{\tau\}$, whereas the lift of the empty join from $\text{Ideal}(R)$ is $\{\tau, e\}$. Hence ambient empty joins are not preserved. Nonempty ambient joins are preserved because their supremum contains a lifted ideal and therefore e ; it is still in the non-bottom subposet.

249.5 4. Correcting the monoid-semiring presentation

The printed presentation in chapter 14 takes the ordinary free monoid semiring $N[M_R]$, where M_R is the multiplicative monoid of $G(R)$, modulo

$$[a]+[b]=[a+b] \text{ for supported } a, b, [x]+[\tau]=[x] \text{ for multiplicative generators } x.$$

These relations do not imply $[\tau]=0$. Evaluate every multiplicative generator at 1 in the Boolean semiring. This is unital and multiplicative; every displayed relation becomes $1+1=1$, but $[\tau]$ maps to $1 \neq 0$. The free monoid-semiring universal property therefore gives a model of the relations in which the missing equation fails.

The repair is to add $[\tau]=0$, or explicitly use a free construction already identifying the absorber with semiring zero. With the extra relation, the proposed inverse $G(R) \rightarrow Q$ preserves zero: τ maps to 0 and supported r to $[r]$. It preserves addition by the supported relation and the zero law, and multiplication and one by the monoid presentation. This inverse and evaluation $Q \rightarrow G(R)$ are identities on generators, hence mutual inverses.

The Lean file checks the multiplicative-generator countermodel and the corrected semiring-lift universal property. It does not construct the entire free monoid-semiring congruence quotient. No existing frozen reader text is silently rewritten.

249.6 5. Scope within the Zeta programme

Chapter 14 already gives the semimodule/linear-join-diagram result and ideal classification. PR #3's Rees continuation explicitly begins above that common support. The present work supplies reusable algebraic structure for that continuation; it does not certify its analytic, arithmetic-trace, purity or positivity claims. No RH statement is asserted.

The source acknowledges classical semiring/semimodule terminology and strong semilattices of groups. No exhaustive priority comparison has been completed. Attribution of this construction to the owner's programme, a new Lean implementation, and a claim of new mathematics are distinct assertions.

Part V

Exact original-source metric and recursive propagation proofs

250 Source enclosures and convergent signed projector control

This chapter incorporates the complete written derivations in the user-supplied continuation following merged PR29. The canonical secant and quotient-variation identities already occur in that PR. The four-projector pairing is the same pairing as AW and SP, with the exact coordinate correspondence proved below. The source sandwich, restriction-loss expression for its Hilbert–Schmidt size, and centered signed enclosure are retained in their full forms. We additionally construct the approximating operator in that enclosure and prove an explicit convergent residual bound. The supplied Lean draft is preserved separately as uncompiled; the mathematical scope here is the written proof.

250.1 The unchanged polynomial and arithmetic source

Fix the actual full packet h , tensor order $k \geq 1$, and its monic cyclic polynomial $\chi = \chi_{h,k}$ of degree $q \geq 1$. Put $E = \mathbb{C}[S]/(\chi)$, $H = \mathcal{P}_{2q}$, and $n = 2q + 1$. All coordinates are the original ascending monomial coordinates. The original analytic source and observation are

$$\begin{aligned} g &= 2\xi, & \mathcal{M}F_h &= g/h, & \mathcal{V}P &= P(D_1 + \cdots + D_k)F_h^{\otimes k}, \\ J^{(k)}\mathcal{V}P &= \eta_{h,k}\pi_\chi P, & \eta_{h,k}[P] &= v_h^{\otimes k}P(A_h^{(k)})1, & v_h &= j_h(g/h), & A_h^{(k)} &= \sum_{i=1}^k A_{h,i}. \end{aligned} \quad (\text{ISM1})$$

Here A_h is multiplication by the original coordinate on $E_h = \mathbb{C}[s]/(h)$. Thus the domain of $\eta_{h,k}$ is E , its codomain is $E_h^{\otimes k}$, and its full unit is retained. The minimal polynomial definition of χ on the cyclic vector 1 proves that $[P] \mapsto P(A_h^{(k)})1$ is injective; multiplication by the invertible $v_h^{\otimes k}$ preserves injectivity.

For $N \in \{q-1, q, 2q-1, 2q\}$, let $I_N : \mathcal{P}_N \hookrightarrow H$ be coefficient inclusion, $B_N : \mathcal{P}_{N-q} \rightarrow H$ multiplication by χ followed by inclusion, and $C : E \rightarrow H$ the degree-less-than- q remainder lift in the retained quotient basis. The relation space is zero when $N = q-1$. Polynomial division by the monic χ proves the exact sequence

$$0 \longrightarrow \mathcal{P}_{N-q} \xrightarrow{\times\chi} \mathcal{P}_N \xrightarrow{\pi_\chi} E \longrightarrow 0. \quad (\text{ISM2})$$

Indeed division writes every polynomial uniquely as $\chi Q + r$, $\deg r < q$; if its class is zero, $r = 0$. This also proves injectivity of the relation map and every dimension used below.

Let M_0, M_1 be the actual positive definite Hermitian forms on this same H . In the arithmetic comparison these are the moments of $r_{1/4}^{*k}(y) dy$ and $w_h^{*k}(y) dy$ in $S = k/2 + iy$, with $w_h(y) = |(g/h)(1/2 + iy)|^2/(2\pi)$. The finite identities below also hold for any two positive forms on this unchanged presentation. The canonical section, its relation coefficient, and its positive quotient Gram are

$$\begin{aligned} Z_N(M) &= (B_N^* M B_N)^{-1} B_N^* M C, \\ \rho_N(M) &= C - B_N Z_N(M) : E \longrightarrow H, \\ G_N(M) &= \rho_N(M)^* M \rho_N(M), & V_N(M) &= \det G_N(M) > 0. \end{aligned} \quad (\text{ISM3})$$

At $N = q-1$ the first map is the unique map to the zero space and $B_N Z_N = 0$; no preceding inverse is used. For every other degree, injectivity of B_N and positivity of M make its relation Gram positive definite. Direct substitution gives $B_N^* M \rho_N = 0$ and $\pi_\chi \rho_N = 1_E$. Hence ρ_N is injective, which proves positivity of G_N .

250.2 Both scaled secants, with the original boundary terms

Fix one admitted N , write $\rho_a = \rho_N(M_a)$, and put

$$\Delta = \rho_1 - \rho_0 = B_N(Z_N(M_0) - Z_N(M_1)). \quad (\text{ISM4})$$

For every coefficient map $Z : E \rightarrow \mathcal{P}_{N-q}$, the two cross terms in the Gram expansion vanish by $B_N^* M_a \rho_a = 0$, giving

$$(\rho_a + B_N Z)^* M_a (\rho_a + B_N Z) = G_N(M_a) + (B_N Z)^* M_a (B_N Z). \quad (\text{ISM5})$$

Taking $a = 0$, $B_N Z = \Delta$, and then $a = 1$, $B_N Z = -\Delta$, proves

$$\rho_1^* M_0 \rho_1 = G_0 + \Delta^* M_0 \Delta, \quad \rho_0^* M_1 \rho_0 = G_1 + \Delta^* M_1 \Delta. \quad (\text{ISM6})$$

Here $G_a = G_N(M_a)$. Subtracting the displayed matrices without deleting either boundary term yields, for real a, b ,

$$\begin{aligned} G_1 - aG_0 &= \rho_1^* (M_1 - aM_0) \rho_1 + a\Delta^* M_0 \Delta, \\ bG_0 - G_1 &= \rho_0^* (bM_0 - M_1) \rho_0 + \Delta^* M_1 \Delta. \end{aligned} \quad (\text{ISM7})$$

In particular both boundary terms have the positive signs shown. For $0 < a \leq b$ and $aM_0 \preceq M_1 \preceq bM_0$, congruence of positive matrices and (ISM7) give

$$aG_N(M_0) \preceq G_N(M_1) \preceq bG_N(M_0) \quad \text{at every one of the four degrees.} \quad (\text{ISM8})$$

Such finite endpoints always exist: they may be taken to be the smallest and largest eigenvalues of $M_0^{-1} M_1$, which is positive self-adjoint in the original M_0 metric.

Conjugating (ISM8) by $G_N(M_0)^{-1/2}$ places every eigenvalue of the conjugated positive matrix in $[a, b]$. The determinant is its product and logarithm is the sum of the real logarithms, so

$$q \log a \leq \log \frac{V_N(M_1)}{V_N(M_0)} \leq q \log b. \quad (\text{ISM9})$$

Set

$$\mathcal{B}(M) = \log \frac{V_{q-1}(M) V_q(M)}{V_{2q-1}(M) V_{2q}(M)}, \quad \mathcal{C} = \mathcal{B}(M_1) - \mathcal{B}(M_0). \quad (\text{ISM10})$$

There are exactly two positive and two negative terms in $\mathcal{C}$. Applying the upper endpoint in (ISM9) to the positive terms and the lower endpoint to the negative ones, and then reversing these choices, proves

$$|\mathcal{C}| \leq 2q \log(b/a). \quad (\text{ISM11})$$

Consequently a certified common source enclosure $(1 - \varepsilon)\widehat{M} \preceq M \preceq (1 + \varepsilon)\widehat{M}$, $0 \leq \varepsilon < 1$, gives

$$|\mathcal{B}(M) - \mathcal{B}(\widehat{M})| \leq 2q \log \frac{1 + \varepsilon}{1 - \varepsilon}. \quad (\text{ISM12})$$

These are the supplied source-error estimates in their original forms. At these same use sites the stronger previously proved AW/SP estimate must also be retained. For all ordered eigenvalues $\beta_1 \leq \dots \leq \beta_{2q+1}$ of $D = M_0^{-1} M_1$, define its full existing expression

$$\mathcal{L}_q(D) = \log \frac{\beta_{q+2}}{\beta_q} + 2 \sum_{j=1}^{q-1} \log \frac{\beta_{2q+2-j}}{\beta_j}.$$

The sum is empty at $q = 1$. AW's two nested-flag trace estimates, with the exact operator identification (ISM16)–(ISM19), give

$$|\mathcal{C}| \leq \mathcal{L}_q(D) \leq (2q - 1) \log(b/a).$$

For the last inequality every displayed eigenvalue ratio is at most b/a , and its total coefficient is $1 + 2(q - 1) = 2q - 1$. Thus the same source enclosure in (ISM12) also gives the stronger $(2q - 1) \log((1 + \varepsilon)/(1 - \varepsilon))$ bound.

For the actual moment paths of RMT, let J_q be its integral of the pointwise minimum of the full-spectrum, exact trace-norm, overlap, centered Hilbert–Schmidt, and angle bounds. Each bounds the identical derivative (ISM19); the Hilbert–Schmidt member is (ISM26). Taking their pointwise minimum before integrating gives the recursively refined source-error statement

$$|\mathcal{C}| \leq \min\{J_q, \mathcal{L}_q(D), (2q - 1) \log(b/a)\},$$

$$\mathcal{C} \in [J_L - \epsilon_L, J_L + \epsilon_L] \cap [-J_q, J_q] \quad (L \geq 0).$$

Here J_L, ϵ_L are the fully constructed signed center and residual in (ISM31)–(ISM37). Their interval therefore retains its original orientation in this earlier source-error calculation. For generic positive coefficient forms, the full-spectrum, trace-norm, overlap, Hilbert–Schmidt and signed bounds still apply, but the moment-specific angle improvement and its strict moment-positivity proof are used only on the original moment paths. The exact primitive and coefficient support are established in (ISM38)–(ISM43). Scaling a source by $c > 0$ leaves Z_N, ρ_N unchanged and multiplies G_N, V_N by c, c^q , respectively, directly by (ISM3). Thus its four $q \log c$ terms cancel in (ISM10); this proves the scalar invariance without altering any source form.

250.3 The canonical projector is exactly the original difference

Use $x \in [0, 1]$ for the comparison path, retaining the frequency y and all other deformation parameters. Write

$$M_x = (1 - x)M_0 + xM_1, \quad \dot{M} = M_1 - M_0, \quad X_x = M_x^{-1} \dot{M}. \quad (\text{ISM13})$$

Since $M_x X_x = \dot{M} = \dot{M}^*$, this is self-adjoint in the original M_x inner product. Define

$$\begin{aligned} P_N &= I_N (I_N^* M_x I_N)^{-1} I_N^* M_x, \\ Q_N &= B_N (B_N^* M_x B_N)^{-1} B_N^* M_x, \quad Q_{q-1} = 0, \\ \Pi_N &= \rho_N G_N^{-1} \rho_N^* M_x. \end{aligned} \quad (\text{ISM14})$$

Each formula squares to itself and has M_x -self-adjoint adjoint law. The ranges of the first two are $\mathcal{P}_N$ and $B_N \mathcal{P}_{N-q}$; the range of the third is $\rho_N E$. By (ISM2)–(ISM3),

$$\mathcal{P}_N = \rho_N E \perp_{M_x} B_N \mathcal{P}_{N-q}. \quad (\text{ISM15})$$

To prove the equality, subtract $\rho_N \pi_\chi p$ from any $p \in \mathcal{P}_N$; (ISM2) puts the result in the relation range, and (ISM3) proves orthogonality. Therefore the original P_N, Q_N commute with product Q_N , and their orthogonal range decomposition proves the exact operator identity

$$\Pi_N = P_N - Q_N, \quad \text{Tr } \Pi_N = q. \quad (\text{ISM16})$$

The inverse of the range parametrization $\rho_N : E \rightarrow \text{ran } \Pi_N$ is the literal π_χ restricted to that range; both composites are identities by (ISM3). Thus (ISM16) identifies actual maps and their domains, not only their traces.

Define

$$\begin{aligned} \mathcal{A}_x &= \Pi_{q-1} + \Pi_q - \Pi_{2q-1} - \Pi_{2q}, \\ U_x &= Q_{2q-1} + Q_{2q} - Q_q, \\ W_x &= (P_{2q-1} - P_{q-1}) + (P_{2q} - P_q). \end{aligned} \quad (\text{ISM17})$$

Substitution of (ISM16), with $Q_{q-1} = 0$, gives $\mathcal{A}_x = U_x - W_x$ and $\text{Tr } \mathcal{A}_x = 0$. These U_x, W_x are AW's U, W and SP's $\mathcal{R}, \mathcal{P}$, respectively. The source relation matrix is related to AW's unpadded matrix by $B_N = I_N B_N^{\text{AW}}$, so (ISM14) reproduces its actual projections with no sign or metric change.

Differentiating $\pi_X \rho_N = 1$ shows that ρ'_N has image in the original relation space. More explicitly, differentiation of $B_N^* M_x \rho_N = 0$ gives

$$\rho'_N = -B_N (B_N^* M_x B_N)^{-1} B_N^* \dot{M} \rho_N, \quad G'_N = \rho_N^* \dot{M} \rho_N. \quad (\text{ISM18})$$

The second identity follows because the two cross terms containing ρ'_N vanish by the same orthogonality. All these matrices are smooth on the closed interval, since their positive Gram inverses exist there. Jacobi differentiation and cyclicity of finite trace prove

$$\frac{d}{dx} \log V_N = \text{Tr}(X_x \Pi_N), \quad \mathcal{B}'(x) = \text{Tr}(X_x \mathcal{A}_x), \quad \mathcal{C} = \int_0^1 \text{Tr}(X_x \mathcal{A}_x) dx. \quad (\text{ISM19})$$

For the original row $v(y) = (1, S, \dots, S^{2q})$, $\Pi_N M_x^{-1} = \rho_N G_N^{-1} \rho_N^*$. Thus the signed density in PR29 is exactly

$$\kappa_x(y) = v(y) \mathcal{A}_x M_x^{-1} v(y)^*, \quad \int \kappa_x d\mu_x = \text{Tr} \mathcal{A}_x = 0. \quad (\text{ISM20})$$

The first equality keeps the inverse metric that is required by the original coordinate kernel. Integrating against the original signed measure $\mu_1 - \mu_0$ gives precisely (ISM19).

250.4 Restriction losses and the full cross trace

Fix $i \leq j$ among admitted degrees. The map $\rho_i - \rho_j : E \rightarrow \mathcal{P}_j$ has zero remainder, so (ISM2) makes it an original degree- j relation. Orthogonality of ρ_j therefore gives the cross-Grams

$$\rho_j^* M_x \rho_i = G_j, \quad \rho_i^* M_x \rho_j = G_j, \quad G_i - G_j = (\rho_i - \rho_j)^* M_x (\rho_i - \rho_j). \quad (\text{ISM21})$$

The exact reverse restriction on E is $T_{i,j} = G_i^{-1} G_j$. It is positive self-adjoint in G_i , with spectrum in $(0, 1]$, by the last identity. Cyclic trace and the first two identities give

$$\begin{aligned} \text{Tr}(\Pi_i \Pi_j) &= \text{Tr}(G_i^{-1} (\rho_i^* M_x \rho_j) G_j^{-1} (\rho_j^* M_x \rho_i)) \\ &= \text{Tr}(G_i^{-1} G_j), \\ \text{Tr}((\Pi_i - \Pi_j)^2) &= 2 \text{Tr}(1 - T_{i,j}). \end{aligned} \quad (\text{ISM22})$$

All traces are finite traces of the original coordinate operators. In particular their spectra are not declared to be arithmetic invariant summands.

Set

$$\begin{aligned} A_0 &= \Pi_{q-1} - \Pi_{2q-1}, \quad A_1 = \Pi_q - \Pi_{2q}, \\ \ell_0 &= \text{Tr}(1 - T_{q-1,2q-1}), \quad \ell_1 = \text{Tr}(1 - T_{q,2q}), \\ Z_x &= \text{Tr}(\mathcal{A}_x^2) = 2\ell_0 + 2\ell_1 + 2 \text{Tr}(A_0 A_1). \end{aligned} \quad (\text{ISM23})$$

This retains the cross term with its actual sign. On the full algebra $\text{End}(H)$, the map $L \mapsto M_x^{1/2} L M_x^{-1/2}$ is an algebra isomorphism with inverse $K \mapsto M_x^{-1/2} K M_x^{1/2}$. It sends the M_x -self-adjoint operators to Hermitian operators, and cyclicity preserves traces of every product. This proves $Z_x \geq 0$ and, from $\|A_0 + A_1\|_{\text{HS}}^2 \leq 2\|A_0\|_{\text{HS}}^2 + 2\|A_1\|_{\text{HS}}^2$, proves

$$0 \leq Z_x \leq 4(\ell_0 + \ell_1). \quad (\text{ISM24})$$

Here and below the Hilbert–Schmidt norm is computed after this exact metric isomorphism; no new source metric is used.

Put

$$c_x = \frac{\text{Tr} X_x}{n}, \quad \Sigma_x = \text{Tr}(X_x^2) - \frac{(\text{Tr} X_x)^2}{n}. \quad (\text{ISM25})$$

The trace is real by self-adjointness. Expanding $\text{Tr}((X_x - c_x I)^2)$ proves its equality with Σ_x , hence its nonnegativity. Trace zero of $\mathcal{A}_x$, and Cauchy–Schwarz for the two Hermitian images in the preceding isomorphism, give

$$|\mathcal{B}'(x)| \leq S_q(x) := \sqrt{\Sigma_x Z_x} \leq 2\sqrt{\Sigma_x(\ell_0 + \ell_1)}. \quad (\text{ISM26})$$

This bound can be combined pointwise with the existing full-spectrum, exact trace-norm, overlap, and angle bounds on the same $\mathcal{B}'$. It does not replace any smaller available bound.

250.5 A specified signed approximation and its exact residual

For an M_x -self-adjoint, continuous operator Y_x define $E_x = X_x - c_x I - Y_x$. It is self-adjoint too. Expanding the trace and applying the same Cauchy–Schwarz inequality proves the two signed inequalities

$$\text{Tr}(Y_x \mathcal{A}_x) - \sqrt{\text{Tr}(E_x^2) Z_x} \leq \mathcal{B}'(x) \leq \text{Tr}(Y_x \mathcal{A}_x) + \sqrt{\text{Tr}(E_x^2) Z_x}. \quad (\text{ISM27})$$

Every term is real. Integration is legitimate by continuity on the compact interval. We now construct such a Y_x , with its residual controlled from the actual two endpoint forms.

Let $D = M_0^{-1} M_1$, with ordered positive eigenvalues $b_1 \leq \dots \leq b_n$, counted with multiplicity. For this subsection write $B_x^\circ = (1-x)I + xD$, to distinguish it from every original relation matrix. Since $M_x = M_0 B_x^\circ$, direct inversion gives

$$X_x = (B_x^\circ)^{-1}(D - I), \quad \lambda_j(x) = 1 - x + x b_j, \quad \gamma_j(x) = \frac{b_j - 1}{1 - x + x b_j}. \quad (\text{ISM28})$$

Take an M_0 -orthogonal eigenbasis of D . It is also M_x -orthogonal, since on its j -th line M_x multiplies M_0 by $\lambda_j(x) > 0$. Therefore (ISM28) gives the full spectrum of X_x in the original varying metric.

Define the positive scalar and commuting operator

$$a_x = \frac{\lambda_1(x) + \lambda_n(x)}{2}, \quad H_x = I - B_x^\circ / a_x. \quad (\text{ISM29})$$

Their use does not rescale M_x , its moments, or its quotient Grams. The eigenvalues of H_x are $\zeta_j(x) = 1 - \lambda_j(x)/a_x$, and

$$\|H_x\|_{M_x} = \frac{x(b_n - b_1)}{2(1-x) + x(b_1 + b_n)} \leq \vartheta := \frac{b_n - b_1}{b_n + b_1} < 1. \quad (\text{ISM30})$$

Indeed the extrema of $1 - \lambda/a_x$ are equal and opposite at the two endpoints. The displayed scalar function of x has derivative $2(b_n - b_1)/(2(1-x) + x(b_1 + b_n))^2 \geq 0$. This proves the uniform bound, including $x = 0$.

For every integer $L \geq 0$, form the finite matrix polynomial and its centered version

$$\begin{aligned} X_x^{[L]} &= a_x^{-1} \sum_{r=0}^L H_x^r (D - I), \\ Y_x^{[L]} &= X_x^{[L]} - \frac{\text{Tr } X_x^{[L]}}{n} I. \end{aligned} \quad (\text{ISM31})$$

All factors commute with D and are real functions of its self-adjoint operator. They are consequently self-adjoint in both M_0 and M_x . The exact finite geometric-series identity $(I - H_x) \sum_{r=0}^L H_x^r = I - H_x^{L+1}$, together with $B_x^\circ = a_x(I - H_x)$, proves

$$\begin{aligned} R_x^{[L]} &:= X_x - X_x^{[L]} = H_x^{L+1} X_x, \\ E_x^{[L]} &:= X_x - c_x I - Y_x^{[L]} = R_x^{[L]} - \frac{\text{Tr } R_x^{[L]}}{n} I. \end{aligned} \quad (\text{ISM32})$$

No infinite-series interchange is used in this identity. In the original eigenbasis the residual eigenvalues are $\delta_j(x) = \zeta_j(x)^{L+1} \gamma_j(x)$. Thus its exact centered squared size is

$$\mathrm{Tr}((E_x^{[L]})^2) = \sum_{j=1}^n \delta_j(x)^2 - \frac{(\sum_{j=1}^n \delta_j(x))^2}{n}. \quad (\text{ISM33})$$

Both sides are nonnegative, and all multiplicities and signs of the residual eigenvalues are retained. The signed center is $\mathrm{Tr}(Y_x^{[L]} \mathcal{A}_x) = \mathrm{Tr}(X_x^{[L]} \mathcal{A}_x)$ by $\mathrm{Tr} \mathcal{A}_x = 0$. Equations (ISM27), (ISM31)–(ISM33) therefore provide a finite constructed signed center and its exact error.

There is also a uniform elementary error bound for this fixed original pair of forms. Define

$$K_D = \sum_{j=1}^n \left(\frac{|b_j - 1|}{\min\{1, b_j\}} \right)^2. \quad (\text{ISM34})$$

The denominator of $\gamma_j(x)$ is at least $\min\{1, b_j\}$, so (ISM30)–(ISM33) imply $\mathrm{Tr}((E_x^{[L]})^2) \leq \vartheta^{2L+2} K_D$. The nested relation and source flags in (ISM17) give both U_x, W_x eigenvalues $0^{[q]}, 1^{[2]}, 2^{[q-1]}$: the first relation line contributes one, its next $q - 1$ increments contribute two, and the final increment contributes one; the source increments give the same list. In particular both have rank $q + 1$, and each dominates its range projection. Their ranges in dimension $2q + 1$ intersect in dimension at least one. The trace product of the two range projections is at least that intersection dimension, by summing squared projected lengths in an orthonormal basis. For positive operators, increasing a factor cannot decrease the product trace, since $\mathrm{Tr}(T^{1/2}(S' - S)T^{1/2}) \geq 0$. It follows that $\mathrm{Tr}(U_x W_x) \geq 1$. Using their complete spectra, we obtain

$$Z_x = 8q - 4 - 2 \mathrm{Tr}(U_x W_x) \leq 8q - 6. \quad (\text{ISM35})$$

This proof includes $q = 1$, where the multiplicity $q - 1$ is zero.

Set

$$\begin{aligned} J_L &= \int_0^1 \mathrm{Tr}(X_x^{[L]} \mathcal{A}_x) dx, \\ \epsilon_L &= \int_0^1 \sqrt{\mathrm{Tr}((E_x^{[L]})^2) Z_x} dx. \end{aligned} \quad (\text{ISM36})$$

Every integrand is a specified continuous finite matrix expression on the original source path. Integrating (ISM27) with the constructed (ISM31) and the established uniform bound gives

$$J_L - \epsilon_L \leq \mathcal{C} \leq J_L + \epsilon_L, \quad 0 \leq \epsilon_L \leq \vartheta^{L+1} \sqrt{K_D(8q - 6)} \xrightarrow{L \rightarrow \infty} 0. \quad (\text{ISM37})$$

Thus the supplied signed enclosure now has an explicit convergent residual on every fixed original finite source. It retains the arithmetic correlation in its center. The evaluation of the center integral still uses the specified arithmetic entries and a controlled integration method; this calculation supplies no uniform estimate in k . If $b_n = b_1$, then $D = b_1 I$, $H_x = 0$, the residual and $\mathcal{C}$ vanish exactly, and every formula above remains valid.

250.6 The original primitive and the residual at a proper support

We finally prove the source comparison underlying all these metric changes. In the original one-factor complex $V \xrightarrow{\Theta} \mathcal{B}$, retain $h(D)F_h = \Theta \phi_*$, with the original D action commuting with Θ . For $v \in E$, the polynomial $(\rho_1 - \rho_0)v = \chi Q_v$ has the coefficient $Q_v = (Z_N(M_0) - Z_N(M_1))v$ by (ISM4). In the multivariate polynomial ring put

$$f_v(s_1, \dots, s_k) = \chi(s_1 + \dots + s_k) Q_v(s_1 + \dots + s_k). \quad (\text{ISM38})$$

Its image in $E_h^{\otimes k}$ is zero, because $\chi(A_h^{(k)})1 = 0$. Successive monic division in $s_1, \dots, s_k$ constructs specific polynomials $Q_{v,i}$ as follows. Let $f_{v,0} = f_v$ and write $f_{v,i-1} = h(s_i)Q_{v,i} + f_{v,i}$, where $\deg_{s_i} f_{v,i} < \deg h$. Earlier remainder degree bounds are preserved because $h(s_i)$ uses only s_i . The final remainder $f_{v,k}$ has degree below $\deg h$ in every variable and zero class in the quotient, so it is zero by the tensor monomial basis. Telescoping proves

$$f_v = \sum_{i=1}^k h(s_i)Q_{v,i}. \quad (\text{ISM39})$$

This constructs a primitive using precisely the original relations, without replacing them by a larger observation kernel.

In the tensor complex $\mathbf{C}^\bullet = [V \xrightarrow{\Theta} \mathcal{B}]^{\otimes k}$ define

$$K_v = \sum_{i=1}^k (-1)^{i-1} Q_{v,i}(D_1, \dots, D_k) (F_h^{\otimes(i-1)} \otimes \phi_* \otimes F_h^{\otimes(k-i)}) \in \mathbf{C}^{k-1}. \quad (\text{ISM40})$$

The displayed source tensor has exactly $i-1$ preceding factors of degree one. Its differential therefore has sign $(-1)^{i-1}$; multiplying by the sign in (ISM40) gives $+1$. The source operators commute with the differential. Applying $h(D_i)F_h = \Theta\phi_*$ to (ISM39) now proves

$$dK_v = \mathcal{V}((\rho_1 - \rho_0)v). \quad (\text{ISM41})$$

Consequently the two canonical sections have the same class in the original full-source quotient; their common arithmetic observation is exactly $\eta_{h,k}v$ by (ISM1). Composing with the original full-source quotient $q^{(k)}$ gives the already constructed map $\sigma_h^{\otimes k} \eta_{h,k} : E \hookrightarrow Q^{\otimes k}$. Here no map was made natural merely by changing its metric; the actual primitive (ISM40) is the comparison.

To express the full two-leg source without deleting its diagonal, retain the labelled Fourier copy $\widehat{V}$, with the original isomorphism $\mathcal{F} : V \rightarrow \widehat{V}$, and the complex $\mathbf{T}^\bullet = [V \oplus \widehat{V} \rightarrow \mathcal{B}]$, whose differential is $(\phi, \widehat{\psi}) \mapsto \Theta(\phi - \mathcal{F}^{-1}\widehat{\psi})$. There are exact cochain maps from the one-leg complex to this complex with degree-one map identity and degree-zero maps

$$j_+(v) = (v, 0), \quad j_-(v) = (0, -\mathcal{F}v).$$

Indeed either differential equals Θv . The reverse cochain map has degree-one map identity and degree-zero map $p(\phi, \widehat{\psi}) = \phi - \mathcal{F}^{-1}\widehat{\psi}$. Thus $pj_+ = pj_- = 1$, whereas $(j_+ - j_-)(v) = (v, \mathcal{F}v)$ is the full degree-zero diagonal kernel. These formulas prove both composites and retain that kernel explicitly. Tensoring specified choices of these degree-zero maps with their degree-one identities gives cochain maps, since the displayed differential identities preserve each original tensor sign. Apply one such map to (ISM40) to obtain $\widetilde{K}_v \in (\mathbf{T}^{\otimes k})^{k-1}$. Its top differential is still (ISM41).

For precision at a proper declared support $\lambda = (W, S; A)$, let $\mathcal{J}$ be the specified finite carrier of coefficient positions with $A \subseteq \mathcal{J}$. Put $\mathbf{C}_{\text{full}}^\bullet = (\mathbf{T}^{\otimes k})^{\oplus \mathcal{J}}$, with the original differential on each coordinate. Insert the active A -coordinates by literal zero insertion into this fixed full carrier. Let $\mathbf{C}_\lambda^\bullet \subseteq \mathbf{C}_{\text{full}}^\bullet$ be its declared subcomplex, retaining its independent outer label and coefficient mask. The same source primitive is taken in the indicated coefficient copy. When the compared top source representatives lie in $\mathbf{C}_\lambda^k$, their difference has the exact residual

$$[d\widetilde{K}_v]_\lambda \in \frac{d\mathbf{C}_{\text{full}}^{k-1} \cap \mathbf{C}_\lambda^k}{d\mathbf{C}_\lambda^{k-1}}. \quad (\text{ISM42})$$

This quotient is the kernel of the natural map $\mathbf{C}_\lambda^k / d\mathbf{C}_\lambda^{k-1} \rightarrow \mathbf{C}_{\text{full}}^k / d\mathbf{C}_{\text{full}}^{k-1}$: a class maps to zero exactly when its representative is a full-source boundary. The inclusion of the displayed numerator therefore induces the kernel isomorphism, with inverse obtained by using the same representative. These two maps are well-defined since differences in $d\mathbf{C}_\lambda^{k-1}$ are precisely the equivalence relation on both sides.

Thus (ISM41) kills the class at this support exactly when $d\tilde{K}_v \in d\mathbb{C}_\lambda^{k-1}$. Membership $\tilde{K}_v \in \mathbb{C}_\lambda^{k-1}$ is one explicit sufficient witness, not an assumption made for arbitrary W .

First specialize to $k = 1$ and the single coefficient carrier $\mathcal{I} = \{i_0\}$, with active face $A = \{i_0\}$. The coordinate projection onto i_0 and its inverse coordinate insertion identify this one-coordinate carrier with the original one-factor complex. In these specified coordinates put $\mathcal{B}_\lambda = \mathbb{C}_\lambda^1 \subseteq \mathcal{B}$. Suppose the admitted source image under p is $W \subseteq V$, so its boundary range is exactly ΘW , and retain $\Theta V \subseteq \mathcal{B}_\lambda$. The precise kernel map in this single coordinate is

$$V/W \longrightarrow \mathcal{B}_\lambda/\Theta W, \quad [v] \longmapsto [\Theta v]_W. \quad (\text{ISM43})$$

It is injective because Θ is injective: $\Theta v = \Theta w$, $w \in W$, forces $v = w$. Its range is the kernel of the map to the full quotient $\mathcal{B}/\Theta V$, since being in that kernel means being represented by Θv . In this case (ISM42) is exactly the class of the original one-factor primitive in V/W .

For an arbitrary admitted face $A \subseteq \mathcal{I}$, restore the original coordinate injections $\iota_a : \mathcal{B} \rightarrow \mathcal{B}^{\oplus \mathcal{I}}$ and projections $\text{pr}_a : \mathcal{B}^{\oplus \mathcal{I}} \rightarrow \mathcal{B}$. They satisfy $\text{pr}_b \iota_a = \delta_{ab} 1$ and $\sum_{a \in A} \iota_a \text{pr}_a = 1$ on the A -supported subspace. Let the degree-one source at this face be $\mathcal{B}_\lambda^{\oplus A}$, inserted in the fixed carrier by these ι_a , and retain the degree-zero source image $W^{\oplus A}$ and boundary $(\Theta W)^{\oplus A}$. Its kernel map is

$$(V/W)^{\oplus A} \longrightarrow \mathcal{B}_\lambda^{\oplus A}/(\Theta W)^{\oplus A}, \quad ([v_a])_{a \in A} \longmapsto \left[\sum_{a \in A} \iota_a \Theta v_a \right].$$

Replacing v_a by $v_a + w_a$, $w_a \in W$, changes the displayed sum by the specified boundary, so the map is well-defined. If its image is zero, projection by each pr_a gives $\Theta v_a \in \Theta W$, whence $v_a \in W$ by injectivity of Θ . Thus the map is injective. A representative in its codomain maps to zero in $(\mathcal{B}/\Theta V)^{\oplus \mathcal{I}}$ exactly when each active coordinate is Θv_a for some $v_a \in V$. Its inverse on that kernel takes these unique preimages modulo W . Changing a representative by an element of $(\Theta W)^{\oplus A}$ changes each preimage by an element of W . The coordinate identities above then prove both inverse composites. This is the exact $(V/W)^{\oplus A}$ residual, with its full ambient carrier specified.

For $A \subseteq A'$, zero insertion sends the tuple $([v_a])_{a \in A}$ to the same tuple extended by zero; both orders of this insertion and the kernel map give $\sum_{a \in A} \iota_a \Theta v_a$. A signed coefficient permutation sends that sum to $\sum_{a \in A} \epsilon_a \iota_{\sigma(a)} \Theta v_a = \sum_{a \in A} \iota_{\sigma(a)} \Theta(\epsilon_a v_a)$, which proves the same commuting identity with every sign retained. When $A = \emptyset$, the two displayed direct sums and their unique map are zero vector spaces and a zero map at the retained outer label $(W, S; \emptyset)$; the coordinate calculation does not identify that label with external absence. This proves the typed relation to the existing mixed-support quotients while retaining every proper-source residual.

All source identities, projector equalities, scaled comparison signs, and signed estimates above use the same original finite polynomial presentation. Their full primitive and proper support kernel have now been exhibited, so backward and forward propagation can replace weaker metric bounds at their earlier use sites without erasing the older sources or claiming that the arbitrary proper-support residual vanishes.

251 Recursive propagation of the original signed metric bounds

This proof combines the earlier full-relative-spectrum estimate AW16, the exact trace norm and actual-overlap estimates of SP, the supplied centered Hilbert–Schmidt estimate, and the all-degree angle estimate EP17–EP25 on their common original source. Each of those complete proofs is retained in this edition. The construction below carries their pointwise minimum through both the original volume and the exact nonlinear endpoint coordinate, without changing either endpoint form.

251.1 The original source and all four quotient volumes

Fix the original packet h , tensor order $k \geq 1$, monic cyclic polynomial $\chi = \chi_{h,k}$ of degree $q \geq 1$, and

$$H = \mathcal{P}_{2q}, \quad S = k/2 + iy, \quad v(y) = (1, S, \dots, S^{2q}). \quad (\text{RMT1})$$

The coordinates are the original ascending monomial coordinates. The original reference and arithmetic measures are

$$d\mu_0 = r_{1/4}^{*k}(y) dy, \quad d\mu_1 = w_h^{*k}(y) dy, \quad w_h(y) = \frac{|(2\xi/h)(1/2 + iy)|^2}{2\pi}. \quad (\text{RMT2})$$

All their original mass and Taylor-unit factors remain. In particular the exact reference convolution identity is

$$r_{1/4}^{*k} = \frac{c_{1/4}^k}{c_{k/4}} r_{k/4}, \quad c_a = 2^{1-2a} \Gamma(2a), \quad c_{1/4} = \sqrt{2\pi}. \quad (\text{RMT3})$$

Thus these are the same measures in AW and SP. Every argument below also applies to the actual finite-circle comparison when one of the measures is its specified positive atomic measure on this same line and its retained degree- $2q$ Gram is positive definite. That positivity is already proved by the original sampled-source bounds. This statement does not assign moment structure to an arbitrary positive coefficient matrix.

For $0 \leq x \leq 1$ let

$$M_x = \int v(y)^* v(y) d((1-x)\mu_0 + x\mu_1)(y), \quad \dot{M} = M_1 - M_0, \quad C_x = M_x^{-1} \dot{M}. \quad (\text{RMT4})$$

The two positive endpoint forms make M_x positive definite throughout the closed interval. For every original cutoff N , let $I_N : \mathcal{P}_N \rightarrow H$ be coefficient inclusion and $B_N : \mathcal{P}_{N-q} \rightarrow H$ multiplication by χ , followed by inclusion. Negative relation degree means the zero space. Retain the orthogonal projections

$$P_N = I_N(I_N^* M_x I_N)^{-1} I_N^* M_x, \quad Q_N = B_N(B_N^* M_x B_N)^{-1} B_N^* M_x, \quad Q_{q-1} = 0. \quad (\text{RMT5})$$

AW's relation matrix has target $\mathcal{P}_N$, so its exact relation to this one is $B_N = I_N B_N^{\text{AW}}$. Equation (RMT5), after that substitution, is precisely AW4 and SP2. The quotient map remains $J_N : \mathcal{P}_N \rightarrow E = \mathbb{C}[S]/(\chi)$, and its canonical positive quotient Gram is $G_N(x)$. Put $V_N(x) = \det G_N(x)$ and retain the four signs:

$$\mathcal{B}(x) = \log \frac{V_{q-1}(x) V_q(x)}{V_{2q-1}(x) V_{2q}(x)}, \quad U_x = Q_{2q-1} + Q_{2q} - Q_q, \quad W_x = P_{2q-1} - P_{q-1} + P_{2q} - P_q. \quad (\text{RMT6})$$

The relation-first determinant-line formula and differentiation of each of these four determinants give, without commuting their operators,

$$\mathcal{B}'(x) = \text{Tr}((U_x - W_x)C_x). \quad (\text{RMT7})$$

This is the same actual integrand as AW6 and SP7.

251.2 The simultaneous bounds on that integrand

Let $b_1 \leq \dots \leq b_{2q+1}$ be every eigenvalue, with multiplicity, of $D = M_0^{-1} M_1$ in the original M_0 metric. They are positive. Retain

$$c_j(x) = \frac{b_j - 1}{1 - x + x b_j}, \quad d_x = c_{2q+1}(x) - c_1(x), \quad \kappa = \frac{b_{2q+1}}{b_1}. \quad (\text{RMT8})$$

These are the ordered eigenvalues of C_x . Indeed $C_x = ((1-x)I + xD)^{-1}(D - I)$, and differentiation with respect to b_j gives the positive quantity $(1 - x + xb_j)^{-2}$. In particular $\int_0^1 d_x dx = \log \kappa$.

Set $s_x = \dim(\text{ran } U_x \cap \text{ran } W_x)$. The two ranks are $q + 1$ in dimension $2q + 1$, so $s_x \geq 1$. All traces and trace norms below are in the same original M_x metric. Define the two calculated functions

$$\begin{aligned} E_q(x) &= c_{q+2}(x) - c_q(x) + 2 \sum_{j=1}^{q-1} (c_{2q+2-j}(x) - c_j(x)), \\ O_q(x) &= \frac{d_x}{2} \min \left\{ 4q - 2s_x, \sqrt{(2q+1)(8q-4-2\text{Tr}(U_x W_x))} \right\}. \end{aligned} \quad (\text{RMT9})$$

The sum is empty when $q = 1$. The complete nested-flag calculation gives both U_x, W_x the spectrum $0^{[q]}, 1^{[2]}, 2^{[q-1]}$. Decomposing each as the sum of its spectral projections of ranks $q + 1$ and $q - 1$, and applying the ordered projection-trace inequalities, gives $|\mathcal{B}'| \leq E_q$, exactly as in AW15–AW16. For clarity the subtraction of the two bounds cancels the common c_{q+1} only after both sums have been written; it leaves every term displayed in E_q .

Both positive operators dominate the original orthogonal projection onto their common range. Subtracting that same projection from both leaves positive operators with traces $2q - s_x$, whence $\|U_x - W_x\|_1 \leq 4q - 2s_x$. Also their computed spectra give

$$\text{Tr}((U_x - W_x)^2) = 8q - 4 - 2\text{Tr}(U_x W_x). \quad (\text{RMT10})$$

Cauchy–Schwarz on all $2q + 1$ eigenvalues of $U_x - W_x$ gives the second trace-norm bound in (RMT9). Since $\text{Tr}(U_x - W_x) = 0$, subtract $(c_1 + c_{2q+1})I/2$ from C_x in (RMT7). In an M_x -orthonormal eigenbasis of $U_x - W_x$, the absolute value of each diagonal entry of this centered C_x is at most $d_x/2$. Multiplying by the corresponding absolute eigenvalues and summing gives the retained exact trace-norm bound

$$|\mathcal{B}'| \leq T_q(x) := \frac{d_x}{2} \|U_x - W_x\|_1 \leq O_q(x). \quad (\text{RMT10a})$$

The second inequality follows from the two trace-norm estimates just proved. Thus neither of those majorants replaces the original trace norm.

The user's additional supplied projector calculation gives another bound on this same integrand. Define

$$\Sigma_x = \text{Tr}(C_x^2) - \frac{(\text{Tr } C_x)^2}{2q+1}, \quad S_q(x) = \sqrt{\Sigma_x \text{Tr}((U_x - W_x)^2)}. \quad (\text{RMT10b})$$

The nonnegative number Σ_x is the squared Hilbert–Schmidt norm of $C_x - \text{Tr}(C_x)I/(2q+1)$ in the original M_x Hilbert space. The trace of $U_x - W_x$ is zero, so Hilbert–Schmidt Cauchy–Schwarz gives $|\mathcal{B}'| \leq S_q$. Equivalently one may apply the isometry $M_x^{1/2} : (H, M_x) \rightarrow (H, I)$ simultaneously to both operators; conjugation preserves their traces and products and proves the same inequality. This is a calculation with the original metric, not a change of either endpoint source form.

The original crossed quotient pairs are $(q-1, 2q)$ and $(q, 2q-1)$. Retain their full canonical minimum-section angle lists $(\theta_1, \dots, \theta_q)$ and $(\varphi_1, \dots, \varphi_q)$. In the second list, ordered with a smallest angle first, the original ambient dimension forces $\varphi_1 = 0$. The count is proved in EP17–EP25. For the following scalar sums put $a = 2q - 1$ and define the explicitly indexed list

$$\lambda_i = -\log \cos^2 \theta_i \quad (1 \leq i \leq q), \quad \lambda_{q+j-1} = -\log \cos^2 \varphi_j \quad (2 \leq j \leq q).$$

Then $\mathcal{B} = -\log \cos^2 \varphi_1 + \sum_{\nu=1}^a \lambda_\nu = 0 + \sum_{\nu=1}^a \lambda_\nu$. Every additional zero remains in the λ -list, while the designated geometric entry φ_1 is still displayed in the full second list. The exact projection-difference spectra give

$$|\mathcal{B}'(x)| \leq d_x \left(\sin \varphi_1 + \sum_{\nu=1}^a \sqrt{1 - e^{-\lambda_\nu(x)}} \right) \leq a \sqrt{1 - e^{-\mathcal{B}(x)/a}} d_x. \quad (\text{RMT11})$$

The second inequality is concavity of $z \mapsto \sqrt{1 - e^{-z}}$ on $[0, \infty)$, applied to the full a -term list, including its zeros, together with the displayed $\sin \varphi_1 = 0$. Both q -entry lists remain the geometric data; the known zero contribution is kept explicitly in these scalar identities.

The needed strict positivity of $\mathcal{B}$ follows on the actual measures rather than being an additional assumption. If $\mathcal{B} = 0$, both nested quotient pairs have equal minimum spaces. To see every implication, their canonical minimum sections satisfy $G_i - G_j = (R_i - R_j)^* M_x (R_i - R_j) \succeq 0$. Thus each determinant ratio in the crossed pairs is at least one. A zero sum of their nonnegative logarithms makes both ratios one. All eigenvalues of $G_j^{-1/2} G_i G_j^{-1/2}$ are at least one, so determinant one makes every eigenvalue one and $G_i = G_j$. The displayed squared norm then gives $R_i = R_j$ as maps to the same original source H . In the first pair R_{q-1} is the literal degree-less-than- q remainder section. Its equality with R_{2q} puts the constant polynomial 1 in the latter minimum space, which is orthogonal to $\ker J_{2q} = \chi \mathcal{P}_q$. For $\chi(S) = \sum a_j S^j$, put $\chi^{\#k}(S) = \sum \overline{a_j} (k - S)^j$. This belongs to $\mathcal{P}_q$ and equals $\overline{\chi(S)}$ on $S = k/2 + iy$. The asserted orthogonality would therefore give

$$0 = \int \chi(S) \chi^{\#k}(S) d\mu_x = \int |\chi(S)|^2 d\mu_x, \quad (\text{RMT12})$$

contradicting the positive Gram of the nonzero polynomial χ . This proof also covers the specified positive atomic comparison. Thus $\mathcal{B}(x) > 0$ on the entire closed interval.

251.3 Carrying the refined bound through both endpoint coordinates

Define the positive function

$$z_x = a \sqrt{1 - e^{-\mathcal{B}(x)/a}} > 0.$$

With every preceding control retained, set

$$\begin{aligned} A_q(x) &= z_x d_x, \\ J_q &= \int_0^1 \min\{E_q(x), T_q(x), O_q(x), S_q(x), A_q(x)\} dx, \\ I_q &= \int_0^1 \min\left\{d_x, \frac{E_q(x)}{z_x}, \frac{T_q(x)}{z_x}, \frac{O_q(x)}{z_x}, \frac{S_q(x)}{z_x}\right\} dx. \end{aligned} \quad (\text{RMT13})$$

These are actual quantities of the original finite source path. The projections are continuous matrix functions of x . Explicitly $s_x = 2(q+1) - \text{rank}[U_x W_x]$. A rank superlevel set is a finite union of sets where a specified minor is nonzero, hence is Borel. This proves measurability of s_x and of every displayed integrand. Equation (RMT12) and compactness give a positive lower bound for $\mathcal{B}$ on this fixed path. Hence all denominators in I_q are nonzero, and the integrands are finite and bounded. This is a fixed-source statement and asserts no bound uniform in the tensor order.

All five preceding estimates bound the same $|\mathcal{B}'|$. Pointwise comparison followed by the triangle inequality for the integral therefore proves

$$\begin{aligned} |\mathcal{B}(1) - \mathcal{B}(0)| &\leq J_q, \\ J_q &\leq \min\left\{\mathcal{L}_q(D), \int_0^1 T_q(x) dx, \int_0^1 O_q(x) dx, \int_0^1 S_q(x) dx, \int_0^1 A_q(x) dx\right\}. \end{aligned} \quad (\text{RMT14})$$

where the earlier AW13 quantity is retained in full:

$$\mathcal{L}_q(D) = \log \frac{b_{q+2}}{b_q} + 2 \sum_{j=1}^{q-1} \log \frac{b_{2q+2-j}}{b_j} \leq (2q-1) \log \kappa. \quad (\text{RMT15})$$

Indeed integration of each c_j gives $\log b_j$, which proves the first entry of the minimum in (RMT14).

For $B > 0$ let

$$\begin{aligned}\mathcal{H}_a(B) &= 2 \operatorname{arcosh}(e^{B/(2a)}), & \mathcal{H}'_a(B) &= \frac{1}{a\sqrt{1 - e^{-B/a}}}, \\ \mathcal{H}_a^{-1}(z) &= 2a \log \cosh(z/2) \quad (z > 0).\end{aligned}\tag{RMT16}$$

The derivative follows by differentiating the positive real inverse branch of $\cosh$; substitution proves both inverse composites. Applying this exact derivative to each of the five bounds on $\mathcal{B}'$ gives

$$|\mathcal{H}_a(\mathcal{B}(1)) - \mathcal{H}_a(\mathcal{B}(0))| \leq I_q \leq \int_0^1 d_x dx = \log \kappa.\tag{RMT17}$$

Thus the exact trace norm, supplied variance estimate, overlap and full-relative-spectrum information propagate into the nonlinear bound, not only into its linear consequence.

Writing $H_0 = \mathcal{H}_a(\mathcal{B}(0))$, the inverse in (RMT16), extended continuously by value zero at zero, and the additive estimate in (RMT14) give the simultaneous interval

$$\begin{aligned}\mathcal{B}(1) &\geq \max \left\{ 0, \mathcal{B}(0) - J_q, 2a \log \cosh \left(\frac{\max\{0, H_0 - I_q\}}{2} \right) \right\}, \\ \mathcal{B}(1) &\leq \min \left\{ \mathcal{B}(0) + J_q, 2a \log \cosh \left(\frac{H_0 + I_q}{2} \right) \right\}.\end{aligned}\tag{RMT18}$$

The actual $\mathcal{B}(1)$ is strictly positive although the lower bound can equal zero. If $M_1 = cM_0$ with $c > 0$, all the c_j coincide, so $d_x, E_q, T_q, O_q, S_q, A_q, I_q, J_q$ vanish. Each original quotient determinant is multiplied by the same power q of $1 - x + xc$; the four signs then give $\mathcal{B}(1) = \mathcal{B}(0)$, as (RMT18) also states. This includes $q = 1$, for which the ordered sums above are empty and $a = 1$.

Every projection and metric in this argument uses the original J_N, B_N , coefficient basis and source measure. The arithmetic class map $\sigma_h^{\otimes k} \eta_{h,k} J_N$, its complete Taylor unit, and the original theta primitives of differences of minimum sections are unchanged. The proof refines numerical bounds on those exact maps; it introduces no identification between their source kernels or between distinct support labels. The earlier complete AW, SP and EP proofs, together with the explicit correspondences (RMT3)–(RMT7), provide the full input proofs used in this propagation.

251.4 Carrying the constructed signed residual into the endpoint

The complete supplied projector correspondence and its explicit finite approximation are proved in Section 250, (ISM14)–(ISM37). Their notation has the exact identities

$$X_x = C_x, \quad \mathcal{A}_x = U_x - W_x, \quad \Pi_N = P_N - Q_N.$$

For completeness retain the actual finite construction here. For each integer $L \geq 0$, put

$$\begin{aligned}B_x^\circ &= (1 - x)I + xD, & \alpha_x &= \frac{2(1 - x) + x(b_1 + b_{2q+1})}{2}, \\ H_x^\circ &= I - B_x^\circ/\alpha_x, & C_x^{[L]} &= \alpha_x^{-1} \sum_{r=0}^L (H_x^\circ)^r (D - I), \\ R_x^{[L]} &= (H_x^\circ)^{L+1} C_x, & E_x^{[L]} &= R_x^{[L]} - \frac{\operatorname{Tr} R_x^{[L]}}{2q + 1} I.\end{aligned}\tag{RMT19}$$

The symbols $B_x^\circ, H_x^\circ, \alpha_x$ label operators and the scalar in this calculation; they leave every original relation matrix B_N , source metric M_x , and coordinate in (RMT1) in place. Multiplication of the finite geometric sum by $I - H_x^\circ$ gives $C_x - C_x^{[L]} = R_x^{[L]}$ exactly. Every factor is a real function of the same

M_0 -self-adjoint D , hence is self-adjoint in $M_x = M_0 B_x^\circ$ as well. Since the trace of $U_x - W_x$ vanishes, (RMT7) becomes

$$\mathcal{B}'(x) = \text{Tr}(C_x^{[L]}(U_x - W_x)) + \text{Tr}(E_x^{[L]}(U_x - W_x)).$$

Apply Hilbert–Schmidt Cauchy–Schwarz in the original M_x metric to the last term and integrate. Define the specified real numbers

$$\begin{aligned} j_L &= \int_0^1 \text{Tr}(C_x^{[L]}(U_x - W_x)) dx, \\ e_L &= \int_0^1 \sqrt{\text{Tr}((E_x^{[L]})^2) \text{Tr}((U_x - W_x)^2)} dx, \\ \vartheta &= \frac{b_{2q+1} - b_1}{b_{2q+1} + b_1}, \quad K_D = \sum_{j=1}^{2q+1} \left(\frac{|b_j - 1|}{\min\{1, b_j\}} \right)^2. \end{aligned} \tag{RMT20}$$

These are J_L, e_L, ϑ, K_D of (ISM34)–(ISM37) with j_L, e_L used to avoid collision with J_q in (RMT13). The eigenvalues of H_x° have absolute value at most $\vartheta < 1$; those of C_x are the full $c_j(x)$. Thus $\text{Tr}((E_x^{[L]})^2) \leq \vartheta^{2L+2} K_D$, because subtracting the trace mean subtracts a nonnegative square from the full sum of squared residual eigenvalues. The two positive operators U_x, W_x dominate their range projections. Those ranges intersect in dimension at least one, so $\text{Tr}(U_x W_x) \geq 1$, by positivity of the trace product and the squared-length formula for the product of the range projections. Equation (RMT10) gives $\text{Tr}((U_x - W_x)^2) \leq 8q - 6$. The signed estimate and its computed residual are therefore

$$\begin{aligned} j_L - e_L &\leq \mathcal{B}(1) - \mathcal{B}(0) \leq j_L + e_L, \\ 0 \leq e_L &\leq \vartheta^{L+1} \sqrt{K_D(8q - 6)} \xrightarrow{L \rightarrow \infty} 0. \end{aligned} \tag{RMT21}$$

Every integral is a continuous finite matrix expression. This proves convergence for the fixed actual two source forms; no uniformity in k is assumed or inferred.

Let $B_0 = \mathcal{B}(0)$ and retain H_0 from (RMT18). Intersecting the proved intervals, for every $L \geq 0$, gives the propagated endpoint bounds

$$\begin{aligned} \mathcal{B}(1) &\geq \max \left\{ 0, B_0 - J_q, 2a \log \cosh \left(\frac{\max\{0, H_0 - I_q\}}{2} \right), B_0 + j_L - e_L \right\}, \\ \mathcal{B}(1) &\leq \min \left\{ B_0 + J_q, 2a \log \cosh \left(\frac{H_0 + I_q}{2} \right), B_0 + j_L + e_L \right\}. \end{aligned} \tag{RMT22}$$

Indeed each lower entry has separately been proved no larger than the actual endpoint, and each upper entry no smaller. Taking their maximum and minimum therefore preserves both inequalities and yields a nonempty interval containing that endpoint. A numerically integrated center must retain its own integration error before use; (RMT20)–(RMT22) state the exact integrals. The scalar source case has $H_x^\circ = E_x^{[L]} = 0$ and $j_L = e_L = 0$, so it also satisfies (RMT22) exactly.

252 The current arithmetic route and its next calculation

The source chain now supplies an actual $\mathbb{C}[t]$ -module cohomology Q , a finite invariant packet inside that cohomology, a specified nonzero extension class, an original theta boundary for its representative defect, and an exact arithmetic formula for the relative weight form. The local continuation makes that last formula an explicit confluent interpolation problem. These constructions are logically prior to any purity conclusion. The subsequent continuation now supplies certified entries of the original arithmetic moment matrix, the exact finite-compression and infinite-tail resolvent comparison, and a convergence rate for the initial resolvent including its complete off-line jets.

252.1 A single chain of exact comparison maps

For each actual finite packet, retaining every full order, the maps proved in this reader are

$$E = \mathbb{C}[t]/h \xrightarrow{R_{\text{ref}}} \mathcal{B} \xrightarrow{q} Q, \quad J_Z R_{\text{ref}} = 1, \quad DR_{\text{ref}} - R_{\text{ref}}A = \Theta\phi_*\ell.$$

Every admitted polynomial correction keeps these same quotient and jet maps. At its distinguished orthogonal level let $B_{N,u}(t) = (p_{N,u}(t) - R_Z(u)(t))/h(t)$, a polynomial of degree at most m . The complete calculation is

$$\begin{aligned} d\nu_Z(t) &= \left| \frac{g(1/2 + it)}{h(1/2 + it)} \right|^2 \frac{dt}{2\pi}, \quad N = d + m, \quad C_N P = j_h P, \quad K_N = C_N (H_N^\nu)^{-1} C_N^*, \\ p_{N,u} &= (H_N^\nu)^{-1} C_N^* K_N^{-1} U_\varepsilon u, \quad R_m u = R_{\text{ref}} u + \Theta(B_{N,u}(D)\phi_*), \\ G_m &= U_\varepsilon^* K_N^{-1} U_\varepsilon, \quad W_m = U_\varepsilon^* K_N^{-1} (AK_N + K_N A^* - K_N) K_N^{-1} U_\varepsilon. \end{aligned} \quad (\text{R1})$$

The middle line evaluates the specified polynomial at the original D ; every source vector lies in V .

The quotient in this statement is the full-source quotient q . At a proper original source $W \subseteq V$, the same correction $R = s_h + \Theta T$ has the exact class

$$[Ru]_W - [s_h u]_W = \eta_W([Tu]_W), \quad \eta_W : V/W \longrightarrow \mathcal{B}_\Omega/\Theta W, \quad [v] \longmapsto [\Theta v]_W. \quad (\text{R1a})$$

Injectivity of Θ proves injectivity of η_W , and subtracting the original source functions proves the equality. Thus every independent coefficient face retains the kernel $(V/W)^a$ before passing to q , including its specified outer leg label and its empty-coefficient endpoint. The complete quotient and support maps are (D9)–(D13).

For the finite sources $W_m^{\text{src}} = \text{span}\{\phi_*, D\phi_*, \dots, D^m \phi_*\}$, which are the spaces denoted W_m in (TB.37)–(TB.39), the generator has type

$$\overline{D} : \mathcal{B}_\Omega/\Theta W_m^{\text{src}} \longrightarrow \mathcal{B}_\Omega/\Theta W_{m+1}^{\text{src}}. \quad (\text{R1b})$$

It is well-defined because $DW_m^{\text{src}} \subseteq W_{m+1}^{\text{src}}$ and $D\Theta = \Theta D$. The full primitive (TB.35) belongs to W_{m+1}^{src} , and $R_{m+1} - R_m \in \Theta W_{m+1}^{\text{src}}$. Taking their original quotient classes therefore gives

$$\overline{D}[R_m u]_{W_m^{\text{src}}} = [R_{m+1} A u]_{W_{m+1}^{\text{src}}}, \quad [K_{R_m} u]_{W_m^{\text{src}}} = -[D^{m+1} \phi_*]_{W_m^{\text{src}}} d_m u. \quad (\text{R1c})$$

The second equality follows from the monic Q_{m+1} and degree- m Q_m in the full source formula (TB.35). These exact source-transition identities accompany the unchanged Grams in (R1); the actual lower source term and full two-row observation remain in (TB.35)–(TB.36).

Write $v_n = j_h q_n$ and $\kappa_n = \|q_n\|_{\nu_Z}^2$. The original arithmetic measure now determines the exact quantity

$$\epsilon_m = \frac{|\text{Re}(v_N^* K_N^{-1} v_{N+1})| + \sqrt{(v_{N+1}^* K_N^{-1} v_{N+1})(v_N^* K_N^{-1} v_N) - (\text{Im}(v_N^* K_N^{-1} v_{N+1}))^2}}{\kappa_N}. \quad (\text{R2})$$

The proofs in Section 9 establish (R1)–(R2) before passing to cohomology. For a reflection-stable packet the first absolute-value term is zero by the exact trace identity. The same sequence obeys

$$\epsilon_m \geq \sum_{\rho \in Z} m_\rho |\text{Re } \rho - \tfrac{1}{2}|. \quad (\text{R3})$$

Thus the rank-two boundary detects the combined displacement of the entire packet, not only its largest individual displacement. The estimate concerns the distinguished R_m sequence. The larger family of all polynomial source corrections has the separately proved metric image and sharp infimum in Section 8; those results do not identify its arbitrary member with R_m .

The full two-row source observation in Section 9 is injective after the original A -iterates are retained. It therefore offers a finite arithmetic calculation preserving every nilpotent jet: compute the source moments, the adjacent monic polynomials and their complete residue vectors, rather than discard a component whose scalar trace vanishes.

252.2 Topology, duality and the two sides of a weight estimate

The actual source moments now have the absolutely convergent incomplete-gamma expression and explicit double-tail bound of Section 7. Its certified six-by-six Gram matrix concerns the original $|2\xi|^2 dt/(2\pi)$ measure. The exact identity (AM.19) supplies the original monic recurrence norms through degree five, with interval enclosures.

For the $|g/h|^2$ kernel, Section 10 proves a universal polynomial quadrature formula, including centres that coincide with a quadrature node. On the precise nonintersection domain its alternate expression is

$$K_{n-1} = \kappa_{n-1}^{-1} q_n(A) S_n q_n(A)^*, \quad AS_n + S_n A^* - S_n = cr_n^* + r_n c^*, \quad r_n = F_n(A)c.$$

The exact Schur comparison (KR.15)–(KR.20) then joins the initial and terminal observations to the actual infinite-dimensional tail. Section 11 proves the explicit initial-resolvent rate (GC.8) and its complete finite-algebra bound (GC.23). The projection to that off-line domain retains the critical summand as its stated kernel. All factors in the Schur identity remain in converting the initial estimate to the terminal form that determines ϵ_m .

In particular, Section 13 identifies exactly the two contributions in a reflection-stable packet:

$$\epsilon_m^2 = 2 \sum_{\rho \in Z} m_\rho (\operatorname{Re} \rho - 1/2)^2 + \mathfrak{d}_{G_m}(A).$$

Its full-jet inequalities also quantify the required metric ratios along each retained nilpotent chain. These identities do not infer a relative estimate from absolute matrix shrinkage.

The theta-polynomial span is dense in every finite differential graph norm. The completed jet graph, however, is $\mathcal{H}^{(r)} \oplus E$, with quotient E , not a quotient of $\mathcal{H}^{(r)}$ in which the arithmetic component has vanished. This supplies the exact comparison between the shrinking Hilbert representative and its unchanged cohomological class.

The exponential observation norm supplies a second exact comparison. A Mellin jet at ρ is bounded precisely in the strip

$$|\operatorname{Re} \rho - \tfrac{1}{2}| < a,$$

with the factorial norm in Theorem 104.3. The original differential then has the energy term $2a \operatorname{sgn}(\log x)$ in Theorem 104.5. Consequently stronger topology and weight control are related by that explicit term; choosing a positive observation norm does not remove it.

For any packet Z , reflection gives the conjugate-linear ring isomorphism

$$\dagger_Z : E_Z \longrightarrow E_{Z^\dagger}, \quad f^\dagger(s) = \overline{f(1 - \bar{s})}, \quad Z^\dagger = \{1 - \bar{\rho} : \rho \in Z\},$$

with all multiplicities retained. In fact $h_Z^\dagger = (-1)^d h_{Z^\dagger}$; this proves well-definedness, and applying the same operation twice is the identity. Restrict the following internal residue pairing to reflection-stable Z , so that this map is an involution on E_Z . The arithmetic residue form is the source form

$$\mathcal{R}_Z(f, u) = \sum_{\rho \in Z} \operatorname{Res}_\rho \frac{f^\dagger u}{g} ds.$$

Its Jacobian contraction is

$$\mathcal{R}_Z(f, g'u) = \sum_{\rho \in Z} m_\rho \overline{f(1 - \bar{\rho})} u(\rho). \quad (\text{R4})$$

Indeed locally $g = z^{m_\rho} w(z)$ gives $g'/g = m_\rho/z + w'/w$, proving (R4) with multiplicities. The trace form pairs reflected centres and can retain nontrivial null directions from nilpotents. In the retained basis $1, t, \dots, t^{d-1}$, define

$$S_{ij} = \sum_{\rho \in Z} \operatorname{Res}_\rho \frac{(s^i)^\dagger s^j}{g(s)} ds, \quad 0 \leq i, j < d, \quad J_g = M_{j_h g'}.$$

Changing representatives by h makes the local quotient by g holomorphic, proving that this matrix represents the intrinsic form. By (R4) the trace pairing has matrix SJ_g . Its exact comparison to the positive source metric is therefore $G_m^{-1}SJ_g$, since $f^*G_m(G_m^{-1}SJ_g)u = f^*SJ_gu$. Its positivity is an arithmetic question about this operator, not a consequence of the positive Gram construction.

The finite-field two-sided weight theorem remains a source for methods, with its compact-support comparison, duality and tensor hypotheses. This reader has not constructed a realization meeting those geometric hypotheses for the entire arithmetic quotient. It has instead calculated the current characteristic-zero objects and their original maps, including the local-cohomology spectral extraction and meromorphic complement documented in the complete finite-comparison appendix.

252.3 Provenance and mathematical status

The coherent interpolation now has the full coefficient identity $J_{h,N} = U_{v_h}C_N$, with $v_h = j_h(g/h)$ and $\varepsilon_h = v_h^{-1}$. Equations (CT.3)–(CT.7) prove equality with (R1), including the original representative, and compatibility with the complete CRT injections between finite packets. The actual reflection preserves the unique minimum and proves the same-metric signed pairing of (CT.10) and (CT.16a).

On the original tensor complex, the complete calculation is

$$\begin{aligned} E^{(k)} &= E_h^{\otimes k}, & A^{(k)} &= \sum_{j=1}^k A_{h,j}, & \mathcal{I}_{h,k,M} &= \mathcal{P}_M^{(k)} \cap (h(s_1), \dots, h(s_k)), \\ R_M &= (I - P_{\mathcal{B}_M})s_h^{\otimes k}, & G_M &= (J_{k,M}M_{k,M}^{-1}J_{k,M}^*)^{-1}, \\ W_M &= -(Y_M^*C_M + C_M^*Y_M), & G_M - G_{M+1} &= Y_M^*Y_M, & Y_M, C_M &: E^{(k)} \longrightarrow \mathcal{E}_M, \\ \dim \mathcal{E}_M &= \binom{M+k}{k-1}. \end{aligned} \tag{R5}$$

Section 14 proves the original ordered division, both cochain signs, every layer map, and the extra orthogonal projection required when tensor packets are enlarged. Its formula (CT.18) calculates the resulting change in both G and W .

For a reflection-stable packet, let p_M be either signed inertia of W_M , and let $\mathfrak{d}_M^{(k)}$ be its complete tensor departure from (CT.20). The same source layers give

$$\begin{aligned} \mathcal{D}_k &\leq p_M \epsilon_M, & p_M \epsilon_M^2 &\geq 2kd^{k-1} \sum_{\rho \in Z} m_\rho (\operatorname{Re} \rho - 1/2)^2 + \mathfrak{d}_M^{(k)}, \\ p_M &\leq \min\{\operatorname{rank} Y_M, \operatorname{rank} C_M, \lfloor d^k/2 \rfloor\}, & \mathcal{D}_k^2 &\leq \operatorname{Tr}(G_M^{-1}(G_M - G_{M+1})) \operatorname{Tr}(G_M^{-1}C_M^*C_M). \end{aligned} \tag{R6}$$

The zero-inertia case is proved directly in (CT.25). The full ordered sum $\mathcal{D}_k$ and all multiplicities are retained in (CT.20). The joint density and exact graph closure in Section 15 show $G_M \downarrow 0$ for this actual total-degree sequence and identify every retained jet in the vertical fibre of (JD.11). The same section proves the coercive inverse-interpolation limit with its arithmetic unit, the supported-zero limit morphism, and the accumulated determinant cost (JD.14)–(JD.15). These formulas connect the relative layer energy to the exact rate of determinant loss through the same original matrices.

The September 11 support, Rees, comparison and audit packages are retained in the companion source directory. The current analytic baseline is the September 12 sequence: finite operator comparison (PR 8), chain descent (PR 9), global retraction (PR 10), homotopy control (PR 11), formal tau recovery (PR 12) orthogonal boundary control (PR 13), and coherent interpolation with joint tensor boundaries (PR 14). Part II includes the complete selected source proof notes with their exact revisions. Historical statements that a map remains unconstructed belong to their stated source dates; a later explicit construction in this reader or the source chain supersedes that particular statement.

The new local proofs are the full support-index equivalence, the corrected carrier and sector comparisons, the arithmetic confluent-kernel minimum and complete two-row source observation, the

classification of source-metric images and aggregate control, and the graph/weighted-jet comparison. The next tranche adds the certified original theta-moment series and its full truncation bound, the confluent quadrature and finite/terminal/tail resolvent identities, the explicit initial convergence rate, and the metric-departure and nilpotent-chain identities. The recovered June 24 historical packet calculation is reproduced with a full-jet comparison in Section 2. Its exact A -invariant saturation is every off-axis local factor; the quotient, involutions, source-metric transport and split-zero endomorphism descent are proved there. The original transcript excerpt and its response locators are retained in the source package. This is an explicitly recorded historical recovery, with its new arithmetic saturation proof distinguished from the original permutation calculation. The subsequent historical reconstruction in Section 3 proves the inverse map from a complete local Hurwitz zero-cluster germ to every moment of its original compact probability measure, followed by the explicit Bernstein recovery of that measure. The monic cluster polynomial retains arbitrary zero multiplicity. The same section proves the complete Laurent period maps and their collision kernels. For two distinct primes, the joint Laurent map is surjective onto the full finite spectral algebra; Theorem 3.1 gives every primary kernel and the inverse original spectral coordinate, including its truncated logarithm on each nilpotent factor. The factorwise Split-Zero lifts and their exact comparison with the synchronized global lift are proved in (S4)–(S5). Their elementary algebraic and analytic steps are written here. No claim of global mathematical priority follows from finding or proving an identity in this research programme.

The finite validation records distinguish exact symbolic identities, rational calibration models, numerical quadratures and intentionally rejected negative controls. They do not count test methods as theorems or imply analytic certification from an L^2 numerical experiment. The supplied formalization records are also kept separate: successful exact-head CI metadata does not turn the unformalized analytic theta arguments into Lean proofs. No Lean run was performed for this continuation.

The current research calculation includes (R2) on the actual $|g/h|^2$ -moments, with its determinant update and two-row recurrence, together with the topology constants of Theorem 104.3. No uniform arithmetic estimate forcing (R2) to vanish has been established in this reader. RH, GRH and a global purity theorem are not conclusions of it. The exact maps and source constraints above specify the live route on which tandem work can now continue. The next estimate must propagate (GC.8) through (KR.16), retaining q_n^2 , κ_n , a_n , the terminal ratio F_n and the actual tail denominator. The arithmetic moment formulas give an executable source for those finite data. The exact departure identity and the full-jet metric bounds specify what a resulting relative estimate would control in the original packet; no component is removed by changing observation.

The next step of that propagation is now calculated in Section 12. For $u_n = q_n(A)c$, $w_n = q_{n-1}(A)c$, and $M_n = \kappa_{n-1}^{-1}K_{n-1}^{-1}$, let $\beta_n = u_n^* M_n u_n$, and let P_n be the exact M_n -orthogonal projection with kernel $\mathbb{C}u_n$ when $\beta_n > 0$. Put $p_n = P_n w_n$, $z_n = P_n A u_n$. The universal step is

$$\begin{aligned} M_{n+1} &= a_n^{-1} \left(M_n - \frac{M_n u_n u_n^* M_n}{a_n + \beta_n} \right), & \frac{\det G_{m+1}}{\det G_m} &= \frac{a_n}{a_n + \beta_n}, \\ \Delta_{n+1} &= \frac{\beta_n \|z_n + a_n p_n\|_n^2}{a_n(a_n + \beta_n)}, & \epsilon^{(n)} &= |g_Z| + \sqrt{g_Z^2 + \Delta_n}, \quad g_Z = \operatorname{Re} \operatorname{tr} A - d/2. \end{aligned} \tag{R7}$$

Here $m = n - d - 1$. The zero-vector exceptional step is given completely in (KT.14), so critical centres and every polynomial coincidence remain in (R7)'s source calculation. The alternate terminal Gram follows by the exact isometry (KT.15) and recurrence (KT.16). The full scalar-to-matrix extraction uses the doubled off-line algebra and the explicit sequence (KT.23); at a reflected pair its matrix coefficient is exactly $(-1)^l F_n^{[k+l+1]}(\rho)$. Finally (KT.24)–(KT.25) recover these coefficients from the original initial error and tail, with both reciprocal series and all polynomial/norm factors displayed. The remaining energy estimate is therefore attached to the three explicit terms of (KT.11), including their actual cross pairing, on the same arithmetic moment sequence.

For a packet closed under both conjugation and reflection, the original real-coefficient calculation in (KT.28) closes this step in terms of consecutive determinant ratios. With the fixed section metric

G_{-1} retained, put $r_m = \det G_m / \det G_{m-1}$ for $m \geq 0$. Then the actual arithmetic allowance obeys exactly

$$\epsilon_m^2 = a_{d+m+1} \frac{(1-r_m)(1-r_{m+1})}{r_{m+1}}. \quad (\text{R8})$$

The coefficient reality and full reflection trace prove $\gamma_n = 0$ in the original coordinates; (KT.7)–(KT.8) then prove (R8), including zero-step cases. This places the relative quartet control directly on the same monic norm ratios and consecutive Gram determinants as the certified moment problem.

This also gives a direct arithmetic bound for the original tesserine violation channel. Retain the original quartet element

$$Q(\rho) = \rho 1 + (1-\rho)\sigma + \bar{\rho}\kappa + (1-\bar{\rho})\sigma\kappa, \quad \rho = \beta + i\gamma,$$

and its character $c_{-+}(\rho) = 2(2\beta - 1)$, as calculated in the carrier section. If $\gamma \neq 0$, $\beta \neq 1/2$, and Z is this entire four-point zero orbit with common full order μ , then $d = 4\mu$ and for every $m \geq 0$,

$$\mu^2 |c_{-+}(\rho)|^2 \leq \epsilon_m^2 = a_{4\mu+m+1} \frac{(1-r_m)(1-r_{m+1})}{r_{m+1}}. \quad (\text{R9})$$

To prove every coefficient, conjugation and the functional equation preserve the full order, and the four real displacements are $\beta - 1/2, \beta - 1/2, -(\beta - 1/2), -(\beta - 1/2)$. The proved aggregate bound (R3) is therefore $\epsilon_m \geq 4\mu|\beta - 1/2| = \mu|2(2\beta - 1)|$. Squaring and using (R8) gives (R9). The sector morphism on the original supported quartet is precisely

$$G(\chi_{-+}) : G(\mathbb{C}[K_4]) \longrightarrow G(\mathbb{C}), \quad Q(\rho)^\bullet \longmapsto c_{-+}(\rho)^\bullet, \quad \tau \longmapsto \tau.$$

Here $\chi_{-+} = \text{ev}_{-1,+1}$ is the original group character extended linearly; it preserves multiplication because the character does, and hence its displayed G -lift is a semiring morphism. At $\beta = 1/2$ this morphism takes the supported value e ; the same original quartet has phase channel $c_{--} = 4i\gamma$. The orbit then has two distinct points when $\gamma \neq 0$, so its degree is 2μ and (R8) applies with that exact degree; the left-hand side of the sector bound is zero. Thus the arithmetic volume comparison and the supported critical value use the same typed character map, with the phase coordinate retained.

252.4 The original theta norm and the positive arithmetic frontier

The two newly delivered source notes, reproduced completely in the appendices, admit the following exact common formula with (R8). Keep $u_j = (I - P_{L_{j-1}})D^j f_0$, $\mathfrak{h}_j = \|u_j\|^2$, and the original measure $|g|^2 dt / (2\pi)$. The polynomial division and original minimum in (KL.23)–(KL.27) prove, at every full packet,

$$\kappa_{d+j} = \mathfrak{h}_j r_j \quad (j \geq 0), \quad \epsilon_m^2 = \frac{\mathfrak{h}_{m+1}}{\mathfrak{h}_m} (r_m^{-1} - 1)(1 - r_{m+1}) - \mathfrak{h}_{m+1}^2 |c_m|^2 \quad (\text{R10})$$

for reflection-stable packets and $m \geq 0$, where $c_m = d_m G_m^{-1} d_{m+1}^*$ uses the original theta projection rows. The first identity includes $j = 0$ and the fixed section G_{-1} : the actual new-layer vector at that endpoint is exactly f_0 . The row dictionary (KL.30) retains its separate domain $m \geq 0$; its cross term is $\mathfrak{h}_{m+1} c_m = \bar{\gamma}_n$, with $n = d + m + 1$. Both signs and the conjugation are obtained by multiplying those rows against the original inverse metric, including both local-unit matrices. Equation (KL.25) substitutes the first identity in (R10) into the complete terminal energy, proving its second identity. Under conjugation closure the original coefficients are real, so γ_n is real; the reflection trace makes its real part zero. Thus $c_m = 0$ in this case, by precisely the same calculation, with no discarded cross term.

For the full quartet in (R9), this gives the proved chain

$$\mu^2 |c_{-+}(\rho)|^2 \leq \epsilon_m^2 = \frac{\mathfrak{h}_{m+1}}{\mathfrak{h}_m} (r_m^{-1} - 1)(1 - r_{m+1}). \quad (\text{R11})$$

Indeed the order-preserving symmetries establish the hypotheses of (R10) and its vanishing cross term; the lower bound was proved with every multiplicity in (R9). The norms $\mathfrak{h}_j$ are independent of the packet. For $h \mid H$, the original polynomial map $P \mapsto (H/h)P$ is an isometry because $(g/H)(H/h)P = (g/h)P$. Its jets are the old complete jets and zero jets at each added centre. Its fixed representative and all its corrected representatives agree under this insertion, as proved in (KL.28). Thus the common theta sequence in (R11) connects the actual nested-packet maps; the packet dependence remains in the two displayed determinant ratios.

For the tensor frontier, retain the original full column maps $F, E_+ : \mathbb{C}^r \rightarrow E_h^{\otimes k}$ and its original norm diagonal Ω in (AP.4). With G_M the actual total-degree minimum, define

$$\begin{aligned} \mathbf{A} &= \Omega^{-1/2} F^* G_M F \Omega^{-1/2}, & \mathbf{B} &= \Omega^{-1/2} E_+^* G_M E_+ \Omega^{-1/2}, \\ \Gamma_{k,M} &= \max_{|\alpha|=M} \sum_{j=1}^k (a_{\alpha_j+1} + (k-1)a_{\alpha_j}), & \pi_M &= \frac{\det G_{M+1}}{\det G_M}. \end{aligned} \quad (\text{R12})$$

All complete conjugation-and-reflection packets satisfy

$$\epsilon_{k,M}^2 = \lambda_{\max}(\mathbf{A}^{1/2} \mathbf{B} \mathbf{A}^{1/2}) \leq \Gamma_{k,M} \lambda_{\max}(\mathbf{A}) \leq \Gamma_{k,M} (\pi_M^{-1} - 1). \quad (\text{R13})$$

Here the square roots are the explicit metric isometries, with their inverses in (AP.12); the original matrices in (R12) remain part of the formula. The full proof in (AP.7)–(AP.21) starts from the actual linear reflection of the original Mellin source. It places the two frontiers in opposite orthogonal eigenspaces and gives $U^*V = 0$. The relative weight is consequently the two off-diagonal blocks UV^* and its adjoint. Its complete singular-vector decomposition identifies its norm squared with the positive operator in (R13), including all zero vectors. The explicit incidence row sum gives $VV^* \preceq \Gamma I$; the inverse-metric update gives $\pi_M^{-1} = \det(I + UU^*)$. Multiplication of its nonnegative eigenvalue factors proves the two inequalities. For $k = 1, M = d + m$, (R13), (R11), and (AP.23) calculate the same original tesserine bound through its norm, volume, and positive-operator presentations.

252.5 The symmetric summand, the actual relation layer, and support

Every factorial in the symmetric comparison is retained. The literal orbit-sum injection I , its diagonal $D_o = I^*I$, and $L = D_o^{-1}I^*$ in (AP.24) give $G_M^s = I^*G_M I$ and the exact identity $(G_M^s)^{-1} = L G_M^{-1} L^*$. The proof uses permutation invariance of the actual minimum, so that its metric commutes with the projection IL . Hence the original redundant frontier has symmetric maps $F_s = LF, E_s = LE_+$ with the unchanged Ω , and

$$\begin{aligned} \mathbf{A}_s &= \Omega^{-1/2} F_s^* G_M^s F_s \Omega^{-1/2}, & \mathbf{B}_s &= \Omega^{-1/2} E_s^* G_M^s E_s \Omega^{-1/2}, \\ (\epsilon_M^s)^2 &= \lambda_{\max}(\mathbf{A}_s^{1/2} \mathbf{B}_s \mathbf{A}_s^{1/2}) \leq \Gamma_{k,M} ((\pi_M^s)^{-1} - 1), & \pi_M^s &= \frac{\det G_{M+1}^s}{\det G_M^s}. \end{aligned} \quad (\text{R14})$$

Equations (AP.25)–(AP.36) prove all these maps, the full positive and zero spectra, the opposite reflection parities, and the orbit-factorial grouping. In particular the isometry $Q_M = G_M^{1/2} I (G_M^s)^{-1/2}$ satisfies $Q_M^* Q_M = I$ and $Q_M Q_M^* = IL$; it carries the symmetric relative operator to the invariant restriction of the original one, retaining the complementary operator on $\ker L$. The continuous cochain projector in (SS.1)–(SS.9) has exactly this cohomology image. Its finite packet version uses the original section and full jet, and all Koszul signs in that construction remain in its primitive.

The actual next relation layer underlying these matrices is proved in (KL.7)–(KL.20). Its complete graph frame, Gram, fixed-order division primitive, derivative image, and derivative cokernel are given there. The comparison with a homogeneous shell is the exact polynomial identity (KPC.7), with every lower coefficient in (KPC.6). Its full graph is the fibre product (KPC.12), and its two projection kernels are specified in (KPC.11). For two tensor coordinates the original ratio algebra embeds

by (KPC.16), with exponent $\max_{\rho/\sigma=r}(m_\rho + m_\sigma - 1)$ at each coincident ratio. Its adjacent-shell generator action is (KPC.22a); the missing second-coordinate multiplier remains in that formula. The finite example (KPC.23)–(KPC.28a) calculates both original shell ranks, all nine node values, and the actual minimum, establishing the exact scope of that comparison.

For every linear map in these graph, kernel, quotient and cochain comparisons, the fixed-support lift at the end of the projective-comparison section maps (λ, v) to (λ, Tv) and maps external absence to absence. Its scalar and additive identities are proved there, including supported zero. For measured support, the historical branch chapter proves the separate full connection from ordinary branches to frame points through $\text{Idl}(L) \rightarrow L$, with its exact kernel congruence and descent criterion. Its L^∞ correspondence identifies every Boolean branch with a multiplicative state and its normal branches with actual measure atoms. The factor $\mu(a)^{-1} \int_a f d\mu$ is retained. These explicit maps specify the support observations available to the analytic construction and preserve the nonatomic support component alongside its atomic quotient.

252.6 The original derivative cost and both positive-half-line kernels

The same original derivative layer has the stronger arithmetic identity proved in (QD.6)–(QD.15). In its exact metric coordinates, $-\hat{Y}^*\hat{C} = UV^*$ occupies one off-diagonal reflection block. Thus its norm is the full relative allowance, and the original trace cost χ_M , operator cost ζ_M and largest update eigenvalue λ_M satisfy

$$\epsilon_{k,M}^2 \leq \frac{\lambda_M}{1 + \lambda_M} \zeta_M \leq \frac{\lambda_M}{1 + \lambda_M} \chi_M, \quad \epsilon_{1,M}^2 = (1 - \pi_M) \chi_M. \quad (\text{R15})$$

The first two inequalities follow from the norm of the product of the two actual layer maps and the eigenvalues of $UU^*(I + UU^*)^{-1}$. For one factor, the layer is one-dimensional, so that product is the outer product of its two original rows and its norm is exactly their norm product. Its rank-one determinant update is $\pi_M = (1 + \lambda_M)^{-1}$, proving the last equality. This argument includes either row zero. The full lower bounds $4k^2\delta_*^2$ and all finite accumulated volume constraints follow in (QD.10)–(QD.13), with their positive denominators established before division.

For one factor, put $z = s - 1/2$, $x_h = -z^2$, and retain the monic polynomial H defined by $h(s) = (-1)^D H(x_h)$, $d = 2D$. The exact algebra is $A_H \oplus zA_H = \mathbb{C}[x_h, z]/(H, z^2 + x_h)$, with its two local length- m_ρ branches explicitly inverted in (SP.8)–(SP.9). The original source is the Hilbert direct sum for $d\lambda_h = |V(x_h)|^2 dx_h / (2\pi\sqrt{x_h})$ and $x_h d\lambda_h$. Here $v_h(s) = V(x_h)$ is the entire original quotient and its full unit modulo H enters both kernels. With those kernels and their inverse metrics, (SP.23)–(SP.35) give

$$\begin{aligned} \epsilon_{N-d} &= \left\| G_e^{-1/2} (G_o - G_e X) G_o^{-1/2} \right\|, \\ K_e - X K_o &= \begin{cases} f_n e_n^* / p_n, & N = 2n, \\ -f_{n+1} e_n^* / u_n, & N = 2n + 1. \end{cases} \end{aligned} \quad (\text{R16})$$

The first line follows by substituting the exact multiplication matrix $\frac{1}{2}I + \begin{pmatrix} 0 & -X \\ I & 0 \end{pmatrix}$ in the original weight form. The second is its full inverse-metric recurrence: all interior adjacent terms cancel with their original norm ratios, and the last pair has the two displayed parity signs. The finite kernels have indices $(n, n-1)$ and (n, n) , respectively. Hence the norm is given by the full quadratic contractions in (SP.33), with at most one nonzero singular value. Every nilpotent jet remains inside f_n, e_n, X and both metrics. The exact derivative cost (SP.34) identifies (R16) with (R15), including the two zero-frontier cases.

252.7 The gamma determinant and the retained spectral-sum fibre

The original completed function has the exact factorization $g(1/2 + it) = \Gamma(1/4 + it/2)a(t)$, with $a(t) = -\pi^{-1/4}(t^2 + 1/4)e^{-it \log \pi/2} \zeta(1/2 + it)$. The beta integral and generating-function calculation

(TG.7)–(TG.14) prove the reference monic norms $\gamma_n = \sqrt{2} n! \Gamma(n + 1/2)$. Keeping the actual multiplier in the full positive arithmetic Gram matrix gives its determinant D_n , with $D_{-1} = 1$. Monic triangular Gram congruence proves $\mathfrak{h}_n = \gamma_n D_n / D_{n-1}$, so the actual quartet formula is exactly

$$\epsilon_m^2 = (m+1)(m+\frac{1}{2}) \frac{D_{m+1} D_{m-1}}{D_m^2} (r_m^{-1} - 1)(1 - r_{m+1}), \quad m \geq 0. \quad (\text{R17})$$

This follows by substituting the consecutive norm ratio into (R10), whose cross term vanishes by the proved quartet symmetry. The full packet determinants are independently expressed in (TG.17)–(TG.18), and the original confluent kernel is the complete Gram congruence (TG.20)–(TG.22). The explicit triangular maps to the parameter 3/4 family and their inverses retain every phase and degree. The theorem-hypothesis analysis (TG.25)–(TG.28) proves the obstruction from the infinitely many retained critical zeros on positive-measure intervals; it also supplies these exact Gram maps for continuing beyond that obstruction.

The web spectral-sum construction retains an additional relative coordinate $\Delta = (s_1 - s_2)^2$. Write $S = s_1 + s_2$, $Z = S - 1$ and $x_\Sigma = -Z^2$. Its complete reflection components, proved in Section 24, are

$$B_e = \frac{\mathbb{C}[x_\Sigma, \Delta]}{(A_0, x_\Sigma \Delta A_1)}, \quad B_o = \frac{\mathbb{C}[x_\Sigma, \Delta]}{(A_0, \Delta A_1)}. \quad (\text{R18})$$

Here the original polynomial identities are $H_0(S, \Delta) = A_0(x_\Sigma, \Delta)$ and $H_1(S, \Delta) = Z A_1(x_\Sigma, \Delta)$; all coefficients come from $h((S+r)/2) = H_0 + r H_1$, $r^2 = \Delta$. The map $\alpha : B_o \rightarrow B_e$ multiplies by x_Σ , and $\beta : B_e \rightarrow B_o$ is the quotient. They satisfy $\alpha\beta = x_\Sigma$ and $\beta\alpha = x_\Sigma$. The original generator is $S = I + \begin{pmatrix} 0 & -\alpha \\ \beta & 0 \end{pmatrix}$. Their dimensions are $D(D+1)$ and D^2 ; both values follow by taking the symmetric square of the original two D -dimensional reflection eigenspaces. The exact maps, rather than an identification of these unequal spaces, enter the weight.

The full kernel and cokernel of $S - 1$ both recover A_H . Indeed $A_0(0, \Delta) = (-1)^D H(-\Delta/4) \neq 0$ makes α injective, while β is onto. Its cokernel map evaluates $x_\Sigma = 0$ and sends Δ to $-4x_h$. The kernel injection sends $q(x_h)$ to $\Delta A_1 q(-\Delta/4)$ in B_e , with the full polynomial ΔA_1 retained before taking the quotient. The ideal calculation and the dimension count prove both exact sequences in the cited section, including all orders. On both defect modules the actual tensor unit acts as $V(x_h)^2$, because at $S = 1$ the two original arguments are s and $1 - s$. Thus the complete paired packet, its nilpotents and its arithmetic unit remain in the relative fibre.

The exact matrix-weight pushforward retains all powers of Δ , the Jacobian $dx_\Sigma / \sqrt{x_\Sigma}$, and both vector Hilbert measures. Its actual least-norm quotient gives the two metrics in (R18); the upper block of the original weight is $\beta^* G_o - G_e \alpha$, with its full rectangular singular spectrum. All maps preserve external absence and carry a vanishing amplitude to its supported zero through the displayed fixed-support lifts. These finite identities and complete source maps are established without an asymptotic estimate for (R17).

252.8 The sum derivative, its strict normal energy and the full conormal algebra

For the actual sum amplitude retain $a_h^{\text{SC}}(t) = v_h(1/2 + it)/\sqrt{2\pi}$, $w = |a_h^{\text{SC}}|^2$, $\mu_h = \int w$, and $I_h = 4 \int |(a_h^{\text{SC}})'|^2$. In the original coordinates $t_i = u/k + y_i$, $y_k = -\sum_{i < k} y_i$, the full product amplitude is $\Psi = \prod_i a_h^{\text{SC}}(t_i)$ and its squared fibre norm is $m = w^{*k}$. The exact Jacobian has absolute value one. Differentiating before integration gives $\partial_u \Psi = k^{-1} \sum_i a'_i \prod_{j \neq i} a_j$. The mixed integrated terms vanish because $\int \bar{a} a' = 0$. Orthogonal projection onto the actual product-amplitude line gives

$$\int_{\mathbb{R}} \frac{|m'|^2}{m} du + 4 \int_{\mathbb{R}} \|n(u)\|^2 du = \frac{\mu_h^{k-1}}{k} I_h, \quad n = \partial_u \Psi - \frac{m'}{2m} \Psi. \quad (\text{R19})$$

The proof in (FC.1)–(FC.4) retains the original mass and phase, and establishes every required integrability statement. For every finite independent relative polynomial frame, $j_u c = \Psi \sum_\alpha \theta_\alpha(i\mathbf{y}) c_\alpha$,

the corresponding exact derivative is

$$\partial_u(j_u c) = j_u(c' + \Gamma_u c) + N_u c, \quad \Gamma = W^{-1} j^* j', \quad N = (I - j W^{-1} j^*) j', \quad j^* N = 0. \quad (\text{R20})$$

This identity follows by inserting the orthogonal projection onto $\text{im } j_u$, with $W = j^* j > 0$. Its full normal Gram is $\mathcal{N} = N^* N$.

Every finite packet leaves infinitely many critical-line zeros of the original amplitude. At such a zero T of complete order ℓ_T , the transverse expansion in (FC.25) has coefficients $c_T A_b \delta^{\ell_T}$ for Ψ and $(\ell_T/k) c_T A_b \delta^{\ell_T-1}$ for $\partial_u \Psi$, with $c_T A_b \neq 0$. Thus an equality $N_u c = 0$ forces the relative polynomial to vanish on the entire hyperplane $y_1 = T - u/k$ whenever the other factors can be chosen nonzero. For $k \geq 3$ this holds at every u ; for $k = 2$ it holds outside the countable sumset $\mathcal{Z}_h + \mathcal{Z}_h$. Infinitely many such hyperplanes force the finite polynomial to vanish. Consequently (FC.21)–(FC.27) prove

$$\begin{aligned} \mathcal{N}(u) &> 0 \text{ everywhere for } k \geq 3, \\ \mathcal{N}(u) &> 0 \text{ almost everywhere for } k = 2, \quad \int \frac{|m'|^2}{m} < \frac{\mu_h^{k-1}}{k} I_h. \end{aligned} \quad (\text{R21})$$

The full proof retains the orders, coefficient domains and the quartet two-factor zero fibre $N_0 = 0$.

The two-branch transformation is equally exact for a matrix weight which is not even. At $x > 0$, put $v = \sqrt{x}$ and

$$M = \begin{pmatrix} I & ivI \\ I & -ivI \end{pmatrix}, \quad H = \frac{M^* \text{diag}(W(v), W(-v)) M}{2v}.$$

The original coefficient is $c(\pm v) = a(x) \pm ivb(x)$. Equations (FC.10)–(FC.18) prove the full unitary correspondence, the covariant derivative $\nabla_x = \partial_x + \mathcal{A}$, and its energy

$$\begin{aligned} \mathcal{A} &= M^{-1} \text{diag}\left(\frac{\Gamma(v)}{2v}, -\frac{\Gamma(-v)}{2v}\right) M + \text{diag}(0, I/(2x)), \\ \int \|\partial_u(jc)\|^2 du &= 4 \int_0^\infty x (\nabla_x q)^* H \nabla_x q dx + \int_0^\infty q^* Q q dx, \quad q = (a, b). \end{aligned} \quad (\text{R22})$$

Here $Q = M^* \text{diag}(\mathcal{N}(v), \mathcal{N}(-v)) M / (2v)$. The retained Jacobian drift is $\mathcal{A}^* H + H \mathcal{A} = H' + H/(2x)$. The two endpoint traces $a + i\sqrt{x}b$ and $a - i\sqrt{x}b$ must agree at $x = 0$; this is the proved joining condition for the original derivative domain.

The arithmetic derivative has the unital algebra bridge

$$\Phi : P/I^2 \longrightarrow (P/I)[\epsilon]/(\epsilon^2), \quad [p] \longmapsto [p] + \epsilon[\partial_\Sigma p], \quad I = (h(s_1), \dots, h(s_k)), \quad \partial_\Sigma = k^{-1} \sum_i \partial_{s_i}. \quad (\text{R23})$$

The product rule modulo I proves multiplicativity. Its conormal restriction is the row $(a_i) \mapsto k^{-1} \sum_i h'_i a_i$ on $I/I^2 \cong (P/I)^k$. On an ordered local block of lengths m_i , multiplication by h'_i sends the input constant in variable i to $m_i c_i(0) z_i^{m_i-1}$ times that constant. Counting the monomials having at least one top exponent proves its full rank $d^k - (d-r_0)^k$, r_0 the number of distinct packet roots. The kernel and image of the algebra map, including its linear cokernel, are proved in (CW.6)–(CW.11).

For the original monic remainder section $j : P/I \rightarrow P/I^2$, $Z = S - k/2$ and $D_0 = \delta j$, the exact section defect and correction are

$$[Z, D_0] = -I + J, \quad J = \frac{1}{k} \sum_i M_{h'_i} c_i \ell_i = \frac{d}{k} \sum_i P_i, \quad P_i = \frac{1}{d} M_{h'_i} c_i \ell_i. \quad (\text{R24})$$

Here ℓ_i extracts the original s_i^{d-1} coefficient and c_i inserts the constant polynomial in that variable. The identity $\ell_i M_{h'_i} c_i = dI$ proves that the P_i are commuting idempotents. Their complete tensor decomposition gives eigenvalues dj/k with multiplicities $\binom{k}{j} (d-1)^{k-j}$ for $d > 1$, and $J = I$ for

$d = 1$. Its trace is d^k and its rank $d^k - (d - 1)^k$. The explicit factorization (CW.22) through the full conormal row proves the relationship between these two rank formulas.

The complete arithmetic unit $\widehat{U} = [\prod_i v_h(s_i)]_{I^2}$ gives $j_U = \widehat{U} j_U^{-1}$, $D_U = M_{U^{-1}\delta\widehat{U}} + M_U D_0 M_U^{-1}$, and $[Z, D_U] = -I + U j_U^{-1}$. For the actual minimum section j_M , the difference $a_M = j_M - j_U$ is its admitted original relation in I/I^2 ; the correction is exactly $U j_U^{-1} + [Z, \delta a_M]$, with trace d^k . These are the full source maps proved in (CW.23)–(CW.30). In one variable they also give

$$j_U u = (j_h g') \mathcal{R}_Z(1, u), \quad \mathcal{R}_Z(1, u) = \ell(U^{-1}u), \quad \mathcal{R}_Z(1, j_h g') = \sum_{\rho} m_{\rho} = d. \quad (\text{R25})$$

The partial-fraction proof in (CW.32)–(CW.36) retains the full poles before taking residues. Finally $G(\Phi)$ is the proved semiring lift; the derivative is its infinitesimal coefficient map. Thus every relation killed by the quotient retains its supported zero and its explicit derivative observation.

252.9 The full relative limit and the original arithmetic observation

Retain $k \geq 2$ and the nonempty original packet $d = \deg h \geq 1$ throughout this subsection. For two nested relative frames, keep the literal coefficient inclusion E_{LM} and the original matrices of (NT.1)–(NT.37). Their exact connection difference $K_{LM} = \Gamma_L E_{LM} - E_{LM} \Gamma_M$ obeys

$$N_M = j_L K_{LM} + N_L E_{LM}, \quad N_M^* N_M = K_{LM}^* W_L K_{LM} + E_{LM}^* N_L^* N_L E_{LM}. \quad (\text{R26})$$

The cross terms vanish because $j_L^* N_L = 0$. Thus enlarging a frame transfers the first displayed component into its tangent part, with its complete positive Gram retained. The arithmetic exponential bounds and weighted polynomial density proved in (ND.1)–(ND.34) give $\Pi_M \rightarrow I$ strongly on every original relative fibre. For each fixed original source polynomial P , (NN.1)–(NN.22) prove $r_M(P) = (I - \Pi_M) \partial_u(\Psi P) \rightarrow 0$ in the original global L^2 norm. Their normal-image transitions are the explicit contractions $r_M(P) \mapsto (I - \Pi_L) r_M(P) = r_L(P)$; their full derivative-graph transitions keep $\partial_u(\Psi P)$ unchanged and are isometric.

The same proofs retain the actual logarithmic arithmetic observation. The invariant relation $P_{\text{rel}} = \sum_i h(s_i)$ has zero ordinary jet but derivative jet $(U_k/k) \sum_i [h'(s_i)] \neq 0$. For $d = 1$ the sum is k ; for $d > 1$ its distinct highest standard monomials have coefficients d , so it cannot vanish. Its normal seminorm tends to zero, while its algebraic observation remains this specified nonzero vector. The exact split quotient of that zero limiting seminorm sends every supported source to e and external absence to τ ; the nonzero observation therefore cannot factor through that quotient. Its original finite maps and full derivative graph remain. For the changing canonical target metrics the complete comparison is

$$G_M \preceq G_*, \quad B_M = G_*^{-1/2} G_M G_*^{-1/2}, \quad x^* G_M x = (G_*^{1/2} x)^* B_M (G_*^{1/2} x). \quad (\text{R27})$$

The fixed-source limit has not estimated this changing B_M . For $h = 1$ the finite coefficient quotient is zero, so the arithmetic observation above is its zero map; the original analytic source and the fixed-source density and derivative-graph maps remain as in (NN.22). The cyclic/full-frame derivative split and canonical-section difference are proved with all four metric terms in (CM.1)–(CM.19).

252.10 Every relation depth and its full cyclic complement

For the same monic h and $I = (h(s_1), \dots, h(s_k))$, the complete depth calculation (CC.1)–(CC.52) proves

$$I^r \cap \mathbb{C}[S] = (\chi_r), \quad \chi_r(T) = \prod_{\lambda} (T - \lambda)^{\ell_{\lambda,r}},$$

$$\ell_{\lambda,r} = \max_{\sum_i \rho_i = \lambda} \left(1 + \sum_i (m_{\rho_i} - 1) + (r - 1) \max_i m_{\rho_i} \right), \quad (\text{R28})$$

$$C_r = \mathbb{C}[T] / \chi_r \xrightarrow{\eta_r = U_r \alpha_r} A_r = (P/I^r)^{\oplus k}, \quad \Pi_r \eta_r = I, \quad A_r \cong C_r \oplus \ker \Pi_r.$$

The coefficient-extraction formula (CC.13) constructs this retraction, and (CC.10) counts every invariant orbit before taking its trace. The quotient derivative $\delta_r : P/I^{r+1} \rightarrow P/I^r$ and its scalar counterpart satisfy the commuting squares (CC.17). Their full unit term has the proved decomposition $\delta_r \eta_{r+1} = \eta_r(\partial_r + M_{b_r} \rho_r) + \mathcal{N}_r \rho_r$ of (CC.23); its complementary quotient map vanishes exactly when $U_r^{-1} \delta_r U_{r+1} \in \alpha_r C_r$. The first-jet maps, their full kernels, the product-Jacobian factorization, and the exact two-factor parity ideals at every depth are proved in (CC.29)–(CC.51b). An arbitrary weighted multiplier has all four blocks (CC.45); its lower diagonal block is a genuine quotient operator precisely when the lower left block is zero. Thus the earlier weighted-trace language has the exact operator interpretation (CC.45)–(CC.49), with no complementary direction lost.

252.11 Exterior amplification and the arithmetic volume to estimate

For the actual cyclic quotient, keep $A = M_S$, its canonical G_N and $H = G_N^{-1}(A^* G_N + G_N A - k G_N)$. The complete exterior source note proves that H has spectrum $\epsilon, -\epsilon, 0, \dots, 0$. The additive exterior action $A^{[p]}$ and the original unscaled representative $R_N^{\otimes p} \text{Alt}_p$ have source Gram $p!(\det(G_N)_{I,J})_{I,J}$; their control has the same literal factorial and allowance ϵ . On the determinant of the full positive generalized spectral subspace this gives

$$L_{h,k} = \sum_{\Re \lambda > k/2} \ell_\lambda(2\Re \lambda - k) \leq \epsilon_{h,k,N}^{\text{cyc}}. \quad (\text{R29})$$

The full cochain primitive carries the sign $(-1)^{k(j-1)}$ in block j , which the tensor differential repeats; their product is one. Hence this exterior comparison uses the original theta boundary. The cochain idempotent splits full cohomology, while the ordinary trace in (R29) is on the specified finite arithmetic packet.

For the exact complete nonreal quartet polynomial of (E33), with common order m , let $\ell_k = 1 + k(m-1)$. The counted sum grid yields

$$q = \ell_k(k+1)^2, \quad L_{h,k} = 2\delta \ell_k(k+1) \left\lfloor \frac{(k+1)^2}{4} \right\rfloor, \quad N \geq q-1. \quad (\text{R30})$$

The explicit four occupation counts in (E33)–(E34) prove this formula without a noncollision assumption on ordered tuples. In a larger packet it remains a lower bound and the threshold is its actual $\deg \chi_{h,k} - 1$. The equality analysis (E1)–(E36) further proves, in the original metric, with positive spectral projector Q , orthogonal range projection P , and $T = PA(1-P)$,

$$\begin{aligned} \epsilon^2 - L^2 &= \|T\|_{\text{HS}, G_N}^2 + \epsilon^2 \{\det M + \det(I_2 - M)\}, \\ BX - XD &= T, \quad X = (Q - P)|_{\ker P}, \quad X = \int_0^\infty e^{-tB} T e^{tD} dt. \end{aligned} \quad (\text{R31})$$

Here M is the explicit positive compression in (E5)–(E7), and B, D are the original diagonal blocks of A in the orthogonal sum. The finite nilpotent exponential formulas (E15) prove convergence of the integral and that this Sylvester map is invertible. For $L > 0$, equality $L = \epsilon$ is equivalent to $P = Q$, or to $T = 0$. A retained critical Jordan block forces strict inequality. The canonical Gaussian equality calibration (E35)–(E36) proves why positivity of a moment measure alone supplies no further strictness.

Finally the arithmetic matrices themselves give the exact calculation (CV.1)–(CV.12). Set $D_N = \det K_N$ and $\tilde{K}_N = K_{N-1} + b_{N+1} b_{N+1}^* / \omega_{N+1}$. Then

$$\begin{aligned} \epsilon^2 &= \frac{\omega_{N+1}}{\omega_N D_N} \Delta_N, \quad \Delta_N = D_{N+1} + D_{N-1} - D_N - \det \tilde{K}_N, \\ \Delta_N &= \sum_{\substack{I \subset \{0, \dots, N-1\} \\ |I|=q-2}} \frac{|\det[b_I, b_N, b_{N+1}]|^2}{\omega_N \omega_{N+1} \prod_{i \in I} \omega_i} \quad (q \geq 2). \end{aligned} \quad (\text{R32})$$

Determinant multilinearity proves the positive sum, including the singular first-degree boundary, and (CV.10a) constructs its original source vector with norm squared Δ_N and tensor norm squared $q!\Delta_N$. At $N = q - 1$, (CV.11)–(CV.12) give the same control as $\sum_{j < q-1} |\gamma_j|^2 \omega_j / \omega_{q-1}$ in the unchanged orthogonal expansion of χ . Thus the current quantitative expression is $\omega_{N+1} \Delta_N / (k^6 \omega_N D_N)$ along admitted growing degrees. Its limit has not been estimated. The complete lower bound (R30), the positive exterior data (R32), and the changing metric (R27) are retained together for that calculation.

252.12 The original Toda volumes and the complete four-term loss

The Toda continuation now calculates this same quantity from the original source and relation volumes. In the notation proved in (TVB.1)–(TVB.38c), use $k \geq 1$, a nonempty dagger-stable packet with its full zero orders, $q \geq 1$, real $|\theta| < \pi/2$, and $N \geq q$, except at the separately stated $N = q - 1$ endpoint, throughout (R33)–(R34). We retain $c = k/2$, $Z(\theta) = M_h(\theta)^k$ and $Z_\chi = \bar{\chi}(c - i\partial_\theta)\chi(c + i\partial_\theta)Z$. The Hankel determinants $\mathfrak{D}_n = \det[Z^{(a+b)}]_{a,b < n}$ and $\mathfrak{B}_m = \det[Z_\chi^{(a+b)}]_{a,b < m}$ are the actual source and relation Gram determinants. With $m = N - q + 1$ their exact determinant-line map and the rank-one update give

$$\begin{aligned} V_N &= \det G_N = \frac{\mathfrak{D}_{N+1}}{\mathfrak{B}_{N-q+1}}, & \delta_N &= \frac{V_N}{V_{N-1}}, & \alpha_{N+1} &= \frac{\omega_{N+1}}{\omega_N}, \\ \psi_N &= \frac{\text{Tr } A - cq}{i} - \partial_\theta \log V_N, & \frac{b_N^* G_N b_{N+1}}{\omega_N} &= i\psi_N, \\ \epsilon_N^2 &= \alpha_{N+1}(1 - \delta_N)(\delta_{N+1}^{-1} - 1) - \psi_N^2 = \alpha_{N+1} \frac{\Delta_N}{\det K_N}, & N &\geq q. \end{aligned} \quad (\text{R33})$$

Every equality has its complete source, phase and determinant proof in the cited bridge. At $N = q - 1$, the exact replacement remains $\epsilon_{q-1}^2 = (\nu_0 - \omega_q) / \omega_{q-1} - \psi_{q-1}^2$, with $\nu_0 = \|\chi\|^2$; no preceding inverse occurs. The explicit conjugate-linear map (TVB.38b) sends the lower orthogonal projection of χ to the actual positive-minor exterior source vector, with the full squared-norm factor $\det K_{q-1} / \omega_q$.

The two scalar Toda curvatures have full source maps. For $X = (S - c)/i$, the actual least-norm lift satisfies $R'_N = -I_N$, where $I_N = P_{\mathcal{D}_N} X R_N$ and $O_N = (1 - P_N) X R_N$ in the current tilted pairing, where P_N is the tilted source projection onto $\mathcal{P}_N$. With $\beta_m = \nu_m / \nu_{m-1}$ for $m \geq 1$, the proofs of (TVB.17)–(TVB.21) give

$$\begin{aligned} G_N'' - G_N' G_N^{-1} G_N' &= O_N^* O_N - I_N^* I_N, \\ \text{Tr}(G_N^{-1} O_N^* O_N) &= \alpha_{N+1}(1 - \delta_N), & \text{Tr}(G_N^{-1} I_N^* I_N) &= \beta_m - \alpha_{N+1} \delta_N. \end{aligned} \quad (\text{R34})$$

The common subtracted term is present in both positive costs. At the first admitted degree the two costs are α_q and zero, with no negative-index relation norm. Every derivative boundary has the literal cochain primitive (TVB.9), including its tensor signs.

The coordinating Zeta contribution joins the two volume losses with the original spectral coupling. At $\theta = 0$, $N \geq q$ and $L > 0$, let $\mathbf{P}$ be the G_N -orthogonal projection onto the full positive spectral subspace, $\mathbf{C} = \mathbf{P}A(1 - \mathbf{P})$ its restricted coupling, and $M = E^\sharp \mathbf{P}E$, where E embeds the two G_N -unit eigenvectors of $A^\sharp + A - kI$ at $\pm \epsilon_N$. Set $v_N = -\log \delta_N$, $s_N = (v_N + v_{N+1})/2$ and $t_N = (v_{N+1} - v_N)/2$. The complete derivation in (TVB.39)–(TVB.43), using the same metric on both sides, proves

$$\begin{aligned} \alpha_{N+1} \sinh^2 s_N - L^2 &= \alpha_{N+1} (e^{t_N} - \cosh s_N)^2 + \psi_N^2 \\ &\quad + \|\mathbf{C}\|_{\text{HS}, G_N}^2 + \epsilon_N^2 \{\det M + \det(I_2 - M)\}. \end{aligned} \quad (\text{R35})$$

All four terms are nonnegative. In particular the two-step volume lower bound retains $L^2 + \psi_N^2 + \|\mathbf{C}\|_{\text{HS}, G_N}^2$ inside its inverse-hyperbolic-sine expression. The exact Sylvester inverse maps $\mathbf{C}$ to the difference between spectral and orthogonal projectors; its full original nilpotent factors and singular value remain specified. The complete supplied join is also reproduced as a source appendix.

252.13 Certified theta input and a calculated comparison of the two gaps

The theta continuation proves the sector construction and the exact maps

$$h(D)F_h = f_0, \quad w_1(t) = |h(1/2 + it)|^2 w_h(t), \quad M_h(\theta) = 2 \int_1^\infty |F_h(e^{i\theta/2}x)|^2 dx. \quad (\text{R36})$$

The absolute-square integral is for real $|\theta| < \pi/2$; its holomorphic strip continuation is proved in the theta input chapter. The dagger sign, complex Fourier phase, endpoint Jacobian and source factor $g = 2\xi$ are all retained in (TI.1)–(TI.16). The exact incomplete-gamma double series and its explicit infinite-square-tail bounds (TI.19)–(TI.30) supply rigorous interval enclosures for $M_1(0)$, $M_1(1/10)$, $M_1''(0)$ and $a_1^{(k)}/k = M_1''(0)/M_1(0)$. Each displayed rational interval in that proof has width $3 \cdot 10^{-40}$. The certificate adds the proved infinite tail to outward-rounded ball arithmetic; it does not infer an enclosure from precision agreement. The source norm is positive for $h = 1$ while its arithmetic cyclic quotient is zero. The density identity in (R36), and the globally constructed Mellin division, specify the exact passage to packet input without division of a measured zero value by zero. No packet determinant estimate follows from these four seed intervals alone. For the empty packet $h = 1$, the arithmetic quotient is zero and $V_N = 1$ by the empty-determinant convention. For $q = 1$, $\epsilon_N = 0$ at every admitted degree, whereas the upper Toda expression is strictly positive for $N \geq 1$, as proved in the bridge.

Finally (TC1)–(TC13) calculate both gaps in the original Gaussian calibration with mass μ , variance σ^2 , $c = 1/2$ and $\chi = (S - c)^2 - \sigma^2$. The source and quotient coordinate maps are fully displayed there. They give

$$(V_1, V_2, V_3) = \mu^2 \sigma^2 (1, 1/3, 1/11), \quad \epsilon_1^2 = L_{\text{spec}}^2 = 4\sigma^2, \quad \epsilon_2^2 = 16\sigma^2/3, \\ \alpha_3 \frac{(\mathcal{R}_2 - 1)^2}{4\mathcal{R}_2} - \epsilon_2^2 = 49\sigma^2/33, \quad \epsilon_2^2 - L_{\text{spec}}^2 = L_{\text{spec}}^2 \|Q - P\|_{\text{HS}, G_2}^2 = 4\sigma^2/3. \quad (\text{R37})$$

The first gap is precisely the Toda imbalance square; the second has the explicitly calculated spectral/orthogonal projector map. This calibration uses declared polynomial coefficients. The actual growing packet calculation continues with (R33)–(R36), retaining its arithmetic measure and all four terms of (R35).

252.14 Gamma convolution, certified higher input, and the complete quotient comparison

Result R38: an exact analytic and finite coefficient interface. Keep the original $w_h(t) = |g(1/2 + it)/h(1/2 + it)|^2/(2\pi)$ and $r_\lambda(t) = |\Gamma(\lambda + it/2)|^2/(2\pi)$, with $c_\lambda = 2^{1-2\lambda}\Gamma(2\lambda)$. The full Gamma source appendix and the coefficient-join proof construct

$$r_{\lambda,k} = \frac{c_\lambda^k}{c_{k\lambda}} r_{k\lambda}, \quad m_{h,k} = w_h^{*k} = r_{\lambda,k} C_\Sigma(B_{h,\lambda}^{\otimes k}), \quad B_{h,\lambda} = |v_h/\Gamma(\lambda + it/2)|^2.$$

The Hilbert maps $U_\Sigma f = f(\sum t_i)$ and its conditional adjoint C_Σ have the inverse paired decomposition $F \leftrightarrow (C_\Sigma F, (I - U_\Sigma C_\Sigma)F)$. All masses and the relative vector remain. With $\alpha = 2\lambda$,

$$c_{h,j} = \frac{\int b_j^{(\lambda)} w_h}{c_\lambda j! (\alpha)_j}, \quad \mathcal{A}_h(z) = \sum_{j \geq 0} (\alpha)_j c_{h,j} z^j, \quad d_{h,k,n} = [z^n] \mathcal{A}_h(z)^k,$$

the exact finite moment is $\int b_n^{(k\lambda)} m_{h,k} = c_\lambda^k n! d_{h,k,n}$. The original degree- N source and relation Grams at theta zero use $c_{h,0}, \dots, c_{h,2N}$; their derivative of order r uses the list through $2N+r$, through the fully written original- S polynomial test. The analytic join supplied by the Zeta task and proved in the coefficient chapter is

$$\mathcal{A}_h(z) = c_\lambda^{-1} (1 + z^2)^{-\lambda} M_h(\arctan z), \quad |z| < 1, \quad M_h(\theta) = \int e^{\theta t} w_h(t) dt.$$

The specified branches at zero and exponential domination justify all coefficient derivatives. Its inverse uses $M_h(\theta) = c_\lambda \sec^{2\lambda} \theta \mathcal{A}_h(\tan \theta)$ for $|\operatorname{Re} \theta| < \pi/4$, with the analytic branches continued from zero. The complete source appendix is preserved alongside the explicit cochain correction; applying $\mathcal{V}$ to a section difference gives the boundary, and (GP.26)–(GP.27) construct its primitive.

Result R39: certified original moments and signed coefficients. Equations (GS.1)–(GS.40) prove the original theta derivative recurrence

$$P_0(y) = 8y^2 - 12y, \quad P_{r+1}(y) = -2yP'_r(y) + (2y - \tfrac{1}{2})P_r(y),$$

$$\mu_{2r} = 2 \int_1^\infty \left| \sum_{n \geq 1} P_r(\pi n^2 x^2) e^{-\pi n^2 x^2} \right|^2 dx.$$

Their fully specified positive square tail (GS.18) bounds the omitted infinite integer sum at every fixed order. At order two and three, the rigorous rational enclosures are

$$\begin{aligned} \mu_4 &\in [383.2743417173642425544072374791308324300288, \\ &\quad 383.2743417173642425544072374791308324300291], \\ \mu_6 &\in [17946.5273016052076235667646919834204772848931, \\ &\quad 17946.5273016052076235667646919834204772848934]. \end{aligned}$$

The original reference $c_{13/4} = 10395\sqrt{\pi}/(2048\sqrt{2})$ is enclosed separately from the actual mass μ_0 . The complete invertible moment/coefficient map (GS.34)–(GS.35) certifies c_0, c_2, c_4, c_6 and proves $c_4 < 0, c_6 < 0$. Its tensor coefficient of degree six retains all three terms

$$d_{k,6} = kc_0^{k-1}a_6 + k(k-1)c_0^{k-2}a_2a_4 + \binom{k}{3}c_0^{k-3}a_2^3, \quad a_j = (13/2)_j c_j.$$

The accompanying source-cost continuation (GS.41)–(GS.50) proves the first four monic norms h_0, h_1, h_2, h_3 and all three positive ratios $a_j^{(k)} = h_j/h_{j-1}$ from these same moments. In particular, with $\nu = \mu_2/\mu_0$ and the original sum moments $M_j(k)$,

$$a_1^{(k)} = k\nu, \quad a_2^{(k)} = \frac{\mu_4}{\mu_2} + (2k-3)\nu, \quad a_3^{(k)} = \frac{M_6 - M_4^2/M_2}{M_4 - M_2^2/M_0}.$$

The exact polynomial isometry $P(S) \mapsto P(k/2 + iu)$ and its monic phase i^j preserve these norms and prove the original spectral recurrence $SP_j = P_{j+1} + (k/2)P_j - a_j^{(k)}P_{j-1}$. For the source determinant corrections, put

$$Q_N = \frac{X_{N+2}X_N}{X_{N+1}^2}, \quad Q_0 = \frac{2\nu}{13}, \quad Q_1(k) = Q_0 + \frac{\rho}{13k+2}, \quad \rho = \frac{\mu_4}{\mu_2} - \frac{43\nu}{13}.$$

The certified interval for ρ is strictly negative; hence $0 < Q_1(1) \leq Q_1(k) < Q_0$ and $Q_1(k+1) - Q_1(k) = -13\rho/((13k+2)(13k+15)) > 0$. These are exact statements at every tensor degree for the specified source polynomial degrees. The analytic seed has the original zero arithmetic quotient $\mathbb{C}[S]/(1)$ throughout.

Result R40: finite error propagation to the actual consecutive ratio. The exact polynomial coefficient power and test expansion in (GMT.12)–(GMT.17) propagate finite coefficient enclosures into Hermitian source envelopes. The full boundary-resolvent formula (GMT.19)–(GMT.20) carries those actual forms to their least lifts, including the signed quadratic loss and its original theta primitive. Equations (GMT.29a)–(GMT.29b) also certify every coefficient of the least lift and the full representative loss $\hat{R}^* H \hat{R} - G(H)$ by an explicit positive q -dimensional rational upper form. The positive

finite envelopes induce quotient-dimensional determinant enclosures by minimizing on the same affine space of representatives. For $N \geq q$, retain the exact two-degree source block

$$H_+ = \begin{pmatrix} H_- & C_D \\ C_D^* & D_D \end{pmatrix}, \quad W = D_D - C_D^* H_-^{-1} C_D, \quad F_D = J_D - J_- H_-^{-1} C_D, \quad Z_D = F_D^* G_- F_D.$$

Equations (GMT.22)–(GMT.27) prove, in the original coordinates,

$$\frac{V_{N-1}}{V_{N+1}} = \frac{\det(W + Z_D)}{\det W}, \quad a_{N+1} = \frac{\det W}{W_{11}^2}.$$

Applying the same maps to the Gamma reference gives the exact relative correction T_{N-1}/T_{N+1} as the quotient of these two positive ratios. The fully proved auxiliary bounded multiplier $\min(1 + t^2/4, 10001)$ with $\lambda = 1$, $k = 2$, and the declared $\chi(S) = (S - 1)^2 - 2$ has $T_1/T_3 < 1$. Its exact finite tail, rational envelopes, relation matrices, and source/quotient maps are (GMT.32)–(GMT.42). Thus positivity and boundedness alone do not imply relative correction monotonicity. This explicit counterexample is connected to the arithmetic problem by those same coefficient, least-lift, and determinant maps; its auxiliary weight is not assigned the value of an actual zeta packet weight.

Result R41: the complete phase and a strict relative contribution. For the actual complex product $a = \prod_i A_{h,\lambda}(t_i)$, put $a_k = C_\Sigma a$, $b_k = C_\Sigma |a|^2$, and $d_k = b_k - |a_k|^2$. Equations (GP.6)–(GP.11) prove the exact unitary transport of the arithmetic sum projection and its fibre defect. Equations (GP.12)–(GP.13) use the original quartet tail, with its full constant $25 \cdot 2^{2d}/\sqrt{\pi}$, to prove $d_k(u) > 0$ at every real u for $\lambda = 1/4$, $d \geq 4$, and $k \geq 2$. The full complex coefficient transform and its Parseval identity preserve the factors c_λ^k and $n!$. The source matrices and the original quotient satisfy

$$\begin{aligned} M_h &= M_{\text{coh}} + M_{\text{rel}}, & R_h &= R_{\text{coh}} - B_\chi K, \\ K &= (B_\chi^* M_h B_\chi)^{-1} B_\chi^* M_{\text{rel}} R_{\text{coh}}, \\ G_h &= G_{\text{coh}} + K^* B_\chi^* M_{\text{coh}} B_\chi K + R_h^* M_{\text{rel}} R_h. \end{aligned}$$

For every admitted nonzero quartet quotient the last difference is positive definite. The empty boundary at $N = q - 1$ and zero quotient at $q = 0$ retain their explicit separate values. The graph-to-source addition, gamma multiplication, inverse Mellin map, and full jet unit in (GP.24)–(GP.27) reconstruct the original arithmetic observation and its exact supported zero.

The new finite coefficients, strict fibre contribution, and interval certificates therefore enter the same original Toda and exterior quantities in R33–R37. In particular the lower spectral cost and the upper expression are compared in the same G_N , with its volume-imbalance square, phase square, spectral coupling, and projection terms retained. The following arithmetic endpoint continuation proves a norm bound for the original measure and a finite upper comparison at the full amplified degree. Results R42–R46 below give their complete maps and the explicitly calculated gap between the resulting upper and lower volume estimates.

252.15 Arithmetic endpoint estimates and the full reflected relation map

Result R42: the actual monic norm and its exact leading line. The complete arithmetic endpoint source and its analytic audit prove, for the original density and every integer $n \geq k \geq 3$,

$$(\omega_{h,k,2n}/\omega_{h,k,n})^{1/(2n)} \leq C_h n.$$

Here the literal constant C_h is (EP.40), and the original lower convolution envelope is (AU.10), with $B = 42 + 2 \deg h$ and the compact mass ϑ_h^{k-3} unchanged. The complete balanced-window proof strengthens the admitted norm comparison to

$$(\omega_{h,k,n+r}/\omega_{h,k,n})^{1/(2r)} \leq C_h^{\text{bal}} n, \quad n \geq k \geq 3, \quad n/2 \leq r \leq n,$$

with every factor of C_h^{bal} stated in (EP.50b). The analytic proof derives the local zeta mass from its exact ellipse, the entire identity $g = hv_h$ at the selected centres, the three-factor positive convolution, and the monic Legendre norm. It includes the two Laplace values and their factor two before the final root.

Equations (AL.3)–(AL.10) prove the endpoint and metric of the underlying degree map. Multiplication by the original monic χ gives $\mathcal{L}_{n-q} \simeq \mathcal{L}_n$ for $n \geq q$, with squared operator norm ω_n/ω_{n-q} and adjoint coefficient equal to that same positive ratio. At $n = q - 1$ its source is zero and its target is the original one-dimensional leading line. For $n \geq q$, its representative has the complete Pythagorean decomposition

$$\|\mathcal{V}_{h,k}(\chi p_{n-q})\|^2 = \omega_n + \|\mathcal{V}_{h,k}(\chi p_{n-q} - p_n)\|^2.$$

The correction reduces to $-[p_n]_\chi$ and the relation reduces to zero. Thus the degree-line norm, the original source cost and the supported arithmetic zero are connected by the explicit commutative diagrams of the leading-line chapter.

Result R43: exact products, their optimizer, and full window transport. Keep $n \geq q$, $r \geq 1$, $m = n + r$ and $d_j = V_{n+j}/V_{n+j-1}$. The full radius calculation in (EP.1)–(EP.11), including the original complex phase $b_N^* G_N b_{N+1} = i\omega_N \phi_N$, gives

$$\prod_{j=0}^{r-1} (\epsilon_{n+j}^2 + \phi_{n+j}^2) = \frac{\omega_m}{\omega_n} \frac{V_n}{V_m} (1 - d_0)(1 - d_r) \prod_{j=1}^{r-1} (1 - d_j)^2.$$

For the combined budget $\mathcal{B} = -\log(d_0 d_r \prod_{j=1}^{r-1} d_j^2) > 0$, the unique maximizing contraction sequence for this scalar product is

$$d_0 = (1 + 2x)^{-1}, \quad d_r = 1 - 2x, \quad d_j = (1 - x)/(1 + x) \quad (1 \leq j < r),$$

where $0 < x < 1/2$ solves $\mathcal{B} = 2 \operatorname{artanh}(2x) + 4(r - 1) \operatorname{artanh} x$. The proof in (EP.22)–(EP.31) establishes existence, uniqueness, the exact maximum, its strict improvement over the earlier hyperbolic-sine bound when $r > 1$, and rational root certificates. The fixed-four-endpoint optimum, the phase polynomial and the quantitative concavity loss are separately proved in (EP.15)–(EP.21). No assertion that the scalar optimizer is realized by an arithmetic source is needed for the proved bound on the original evaluation map.

The full Hermitian window chapter constructs its Schur matrices W_j, F_j, Z_j and their determinant ratios from the same source coefficients. Its finite metric transport retains the eigenvalue spread and the exact hyperbolic coordinate for the four-volume logarithm. Equations (EP.32)–(EP.38) give the literal evaluation map from those matrices to every d_j , the budget and the product. With H_+, p, e defined in (EP.34), the complete cancellation is

$$\frac{\omega_m}{\omega_n} \frac{V_n}{V_m} = \frac{H_+}{pe} = \frac{\mathfrak{B}_{m-q+1} \mathfrak{D}_n}{\mathfrak{D}_m \mathfrak{B}_{n-q+1}}.$$

The confluent transfer proof (EP.38a)–(EP.38k) constructs the raw-derivative matrices for every node and order, proves their invertibility, and proves $\det F_a / \det V = \mathfrak{B}_a / \mathfrak{D}_a$. The sign of the column shift, all derivative factorials and every power of i remain in that construction. It also proves the theta derivative giving the phase and the exact Gamma-reference ratio $\det F_a / \det F_a^\Gamma = Y_a / X_a$.

Result R44: the necessary central and four-volume costs. For an actual off-line quartet with full common multiplicity m_0 , the retained degree and allowance are

$$q_k = [1 + k(m_0 - 1)](k + 1)^2, \\ L_{h,k} = 2\delta[1 + k(m_0 - 1)](k + 1) \lfloor (k + 1)^2 / 4 \rfloor.$$

The complete local tensor calculation and Hermitian compression proof in (EP.41) give $\epsilon_{h,k,N} \geq L_{h,k}$ and $L_{h,k}/q_k \geq \delta k/2$. At $n = q_k, r = q_k - 1$, write $C_k = \log(V_{q_k}/V_{2q_k-1})$. Combining the just-proved balanced norm estimate with the exact product yields

$$C_k \geq 2(q_k - 1) \log \frac{L_{h,k}}{C_h^{\text{bal}} q_k}$$

and the stronger full phase and contraction penalties of (EP.50c). The exact four-volume identity is

$$\log \frac{V_{q_k-1} V_{q_k}}{V_{2q_k-1} V_{2q_k}} = 2C_k + \log \frac{V_{q_k-1}}{V_{q_k}} + \log \frac{V_{2q_k-1}}{V_{2q_k}}.$$

Both additional logarithms are nonnegative by minimization over nested lift spaces. Substitution of $L_{h,k}/q_k \geq \delta k/2$, division by $q_k \log k$, and $(q_k - 1)/q_k \rightarrow 1$ prove the necessary four-volume lower limit 4 in (EP.50e). The new signed control is now substituted into this same identity. Write $q = q_k$ and retain the arithmetic endpoint losses $E_0 = \log(V_{q-1}/V_q)$, $E_1 = \log(V_{2q-1}/V_{2q})$, and put $\mathcal{B}_{h,k} = 2C_k + E_0 + E_1$. On the original Gamma-to-arithmetic moment path, (FV.M1)–(FV.M18) proves the exact identity $\mathcal{B}_{h,k} = \mathcal{B}_{h,k}^\Gamma + \Delta_{h,k}$ and $|\Delta_{h,k}| \leq \mathfrak{J}_{h,k}$, where

$$\mathfrak{J}_{h,k} = \int_0^1 \min\{S_{\text{AW}}(x), T_q(x), S_{\text{SP}}(x), S_{\text{HS}}(x), (2q - 1) \sqrt{1 - e^{-F(x)/(2q-1)}} d_x\} dx.$$

Here $F(x)$ is the unchanged four-volume function and d_x the full original relative spectral diameter. The full formulas for S_{AW} , S_{SP} , their exact source correspondence and the nonlinear coordinate are proved at that original endpoint site. Equation (FV.M15a) retains $T_q = d_x \|U_x - W_x\|_1/2$ and $S_{\text{HS}} = \sqrt{\Sigma_x \text{Tr}((U_x - W_x)^2)}$, where $\Sigma_x = \text{Tr}(C_x^2) - (\text{Tr} C_x)^2/(2q + 1)$, and proves both bounds on the original metric by midpoint centering and centered Hilbert–Schmidt Cauchy–Schwarz. The last minimum entry is the actual-moment specialization of RMT11. Every entry is retained, including the exact T_q and its majorant S_{SP} . Let $a = 2q - 1$, $H_0 = 2 \text{arcosh}(e^{\mathcal{B}_{h,k}^\Gamma/(2a)})$, and retain the complete $\mathfrak{J}_{h,k}^{\text{nl}}$ of (FV.M15). For every finite truncation $p_N \geq 0$, the exact source dictionary and finite construction in (FV.M16a)–(FV.M16c) give the signed center and residual j_{p_N}, e_{p_N} : these are exactly J_L, ϵ_L of ISM36 with $L = p_N$, and $X_x^{\text{ISM}} = C_x, \mathcal{A}_x^{\text{ISM}} = U_x - W_x$. They obey $j_{p_N} - e_{p_N} \leq \Delta_{h,k} \leq j_{p_N} + e_{p_N}$ and $e_{p_N} \leq \vartheta^{p_N+1} \sqrt{K_D(8q-6)} \rightarrow 0$ for the fixed original pair of forms, with the unchanged ϑ, K_D in (FV.M16b). Their integrals and the source’s own integration errors remain explicit. The simultaneous endpoints are

$$\begin{aligned} \mathcal{B}_{h,k}^{\text{lo}} &= \max\left\{0, \mathcal{B}_{h,k}^\Gamma - \mathfrak{J}_{h,k}, 2a \log \cosh \left(\frac{\max\{0, H_0 - \mathfrak{J}_{h,k}^{\text{nl}}\}}{2} \right), \right. \\ &\quad \left. \mathcal{B}_{h,k}^\Gamma + j_{p_N} - e_{p_N} \right\}, \\ \mathcal{B}_{h,k}^{\text{hi}} &= \min\left\{ \mathcal{B}_{h,k}^\Gamma + \mathfrak{J}_{h,k}, 2a \log \cosh \left(\frac{H_0 + \mathfrak{J}_{h,k}^{\text{nl}}}{2} \right), \right. \\ &\quad \left. \mathcal{B}_{h,k}^\Gamma + j_{p_N} + e_{p_N} \right\}. \end{aligned}$$

Monotonicity of the exact inverse coordinate in (FV.M16)–(FV.M18) and the signed bound give

$$\begin{aligned} \mathcal{B}_{h,k}^{\text{lo}} &\leq \mathcal{B}_{h,k} \leq \mathcal{B}_{h,k}^{\text{hi}}, \\ 4(q-1) \log \frac{L_{h,k}}{C_h^{\text{bal}} q} + E_0 + E_1 &\leq \mathcal{B}_{h,k}^{\text{hi}}, \quad C_k \leq \frac{\mathcal{B}_{h,k}^{\text{hi}} - E_0 - E_1}{2}. \end{aligned}$$

The last two inequalities substitute the retained central lower bound and the exact four-volume identity; neither arithmetic endpoint loss is omitted. The proper-source primitive residual is the exact

tensor intersection quotient (FV.M13), with the one-leg V/W map proved in (FV.M14), so this metric comparison does not erase any proper-source class.

Equations (EP.44)–(EP.48) construct the original relation layer and the exact change of least lift. Its central Gram has largest relative eigenvalue at least $\delta^2 k^2 / (4(C_h^{\text{bal}})^2) - 1$ by (EP.50f). The cochain primitive and supported quotient image are written there for the same representative.

Result R45: an actual arithmetic upper comparison and its calculated gap. The new arithmetic upper-volume chapter constructs the positive measure

$$d\nu_k(u) = a_k e^{-(\pi/2)|u|} (k - 2 + |u|)^{-B} du, \quad a_k = c_h \vartheta_h^{k-3} e^{-(\pi/2)(k-3)},$$

which is dominated by the original $m_{h,k}(u) du$ for $k \geq 3$. The identity on polynomials is contractive and commutes with every original raw jet, remainder and spectral multiplication map. Its moments are the complete positive Gamma-mixture integrals (AU.12). Writing K_N for the original raw-jet kernel, minimization and positive inversion prove

$$0 \leq C_k \leq \log \det K_{2q_k-1}^V - \log \det K_{q_k}.$$

The actual arithmetic moments needed by this bound stop at degree $2q_k$; the comparator moments through $4q_k - 2$ have the explicit positive integral in (AU.12). The exact finite Gamma coefficient map (AU.16) gives the same cutoff on $c_{h,j}$. The two-Laplace-value majorant, positive Cauchy–Binet minor sum, and interval Legendre jet kernel in (AU.17)–(AU.23) supply further proved upper expressions for this same C_k .

The full scalar proof (AU.24)–(AU.33) gives

$$\begin{aligned} C_k \leq \mathcal{U}_k &= (\alpha D + \log 256) q_k^2 \\ &+ \left(\log(XK) + \alpha + \frac{16R_0}{3D} \right) k q_k \\ &+ B q_k \log(1 + (D + 1)q_k) + q_k \log C_{\text{env}}, \end{aligned}$$

where $\alpha = \pi/2$, $R_0 = \sqrt{\delta^2 + \gamma^2}$, $D = \max(1, 2/b, 2R_0)$, $0 < b < \pi/2$, $X = \max(1, M_h(b), M_h(-b))$, $K = \max(1, \vartheta_h^{-1})$, and $C_{\text{env}} = \max(1, 2/(3c_h D))$. All constants and the literal source mass are retained. For $\mathcal{L}_k = 2(q_k - 1) \log(\delta k / (2C_h^{\text{bal}}))$, (AU.32) computes every term of $\mathcal{U}_k - \mathcal{L}_k$, and (AU.33) proves that its quotient by q_k^2 tends to $\alpha D + \log 256 > 0$. This upper estimate leaves the stated gap to the quartet lower estimate. The propagated original-source estimate is the additional bound

$$C_k \leq \mathcal{U}_k^{\text{signed}} := \frac{\mathcal{B}_{h,k}^{\text{hi}} - E_0 - E_1}{2}.$$

Its complete proof (AU.31a)–(AU.31b) transports the unchanged monomial source and original relation by $P(S) \mapsto P(k/2 + iu)$, retaining the factor i^q and every raw derivative factor i^d . This signed entry uses actual moments through $4q$; the original first matrix bound continues to require actual moments only through $2q$. Let $\hat{\mathcal{U}}_k$ be the minimum of this signed entry and all the full bounds in (AU.31b), including the original $\mathcal{U}_k$ and the actual low-degree matrix entry. They bound the same C_k , so

$$\mathcal{L}_k \leq C_k \leq \hat{\mathcal{U}}_k \leq \mathcal{U}_k, \quad 0 \leq \hat{\mathcal{U}}_k - \mathcal{L}_k \leq \mathcal{U}_k - \mathcal{L}_k.$$

The positive limit in (AU.33) belongs to the explicitly displayed old scalar majorant; it is not assigned to this refined minimum. The complete angle, spectral, and overlap integrands remain the actual quantities controlling the newly narrowed finite interval.

The complete auxiliary Lebesgue calculation proves

$$\left| \log(V_q^{\text{aux}}/V_{2q-1}^{\text{aux}}) - \left(\frac{9}{2} \log 3 - 6 \log 2 \right) q^2 \right| \leq 12q \log(8q)$$

for every even $q \geq 2$. Its full-origin-jet quotient is connected to the original grid by the free monic family $\mathbb{C}[t, u] / \prod_{a,b} (u - t\zeta_{ab})^\ell$ in (AU.46)–(AU.48). The original full jets at $t \neq 0$, the merged jet at zero and the source-dependent kernel derivative are all explicit. The displayed auxiliary estimate belongs to its Lebesgue source; the exact derivative gives the change along the family, without assigning the same asymptotic to the arithmetic source.

Result R46: reflected norm, conormal algebra and their complete kernels. For any original monic χ of degree $q \geq 1$, set $\chi^\dagger = (-1)^q \bar{\chi}(k - S)$, $N_\chi = \chi\chi^\dagger$ and $g = \gcd(\chi, \chi^\dagger)$. The reflected relation chapter proves the algebra isomorphism

$$\mathbb{C}[S]/(\chi^2\chi^\dagger/g) \simeq \mathbb{C}[S]/(\chi^2) \times_{\mathbb{C}[S]/(\chi g)} \mathbb{C}[S]/(\chi\chi^\dagger),$$

with its exact sequence, inverse residue construction and original M_S action. The norm map retains $\chi(k/2 + iu) = i^q \psi(u)$ and $N_\chi(k/2 + iu) = i^{2q} \psi(u) \bar{\psi}(u)$. Thus the full union of reflected and original roots, with added orders at overlaps, is the precise general norm-transfer domain.

The kernel coefficient modules have annihilators (χ) and $(\chi^\dagger)$. Equations (RF.19)–(RF.21) prove their conjugate-linear bijection $F([\chi f]_{\chi^2}) = [\chi f^*]_{N_\chi}$ with inverse, $FM_S = (kI - M_S)F$, and the exact transported norm-kernel product. If a_λ, b_λ are the respective root orders,

$$\dim I_N^t = \sum_{\lambda} \max(b_\lambda - (t-1)a_\lambda, 0), \quad t \geq 1.$$

Equations (RF.22)–(RF.26) prove the exact nilpotence index, the persistent reflected-only CRT algebra, and the fully worked mixed example of kernel dimensions 3, 1, 0. Projection sends each specified kernel vector, including the persistent sector's idempotent when present, to supported zero in its original fibre. The same lifted map fixes the external point τ .

Result R47: restriction spectra, actual arithmetic gaps and finite certificates. For every $q - 1 \leq i \leq j$, retain the original quotient kernels K_N , metrics $G_N = K_N^{-1}$ and minimum source lifts R_N . In the actual monic orthogonal coordinates, let $L_{i,j}$ pad source coefficients and let $P_{i,j}$ be the orthogonal endomorphism projection onto its range in $\mathcal{P}_j$. The complete restriction source and the arithmetic join prove

$$T_{i,j} = K_i G_j : (E, G_j) \longrightarrow (E, G_i), \quad L_{i,j} R_i T_{i,j} = P_{i,j} R_j.$$

Let $I_{i,j} : (E, G_i) \rightarrow (E, G_j)$ denote the original identity transport, and let A_i, A_j denote the same original action A on these two specified metric spaces. The return is its metric adjoint. The actual endomorphism $U_{i,j} = T_{i,j} I_{i,j}$ of (E, G_i) has coordinate matrix $K_i G_j$. Its eigenvalues $0 < g_a \leq 1$ are the squared singular values of the source restriction between the two canonical minimum-lift ranges. For the orthogonal projections Π_i, Π_j onto those ranges in the same original source, the join constructs both restricted-product similarities and proves

$$\mathrm{Tr}_{\mathcal{P}_j} |\Pi_i - \Pi_j|^{2m} = 2 \mathrm{Tr}_E ((I - U_{i,j})^m), \quad m \geq 1.$$

Its explicit two-dimensional principal-angle blocks retain all common-range and ambient-zero components.

The original arithmetic action A has the exact reverse-map defect

$$A_i T_{i,j} - T_{i,j} A_j = H_i T_{i,j} - T_{i,j} H_j, \quad H_N = K_N (A^* G_N + G_N A - k G_N).$$

The change of representatives is the complete relation

$$\mathfrak{d}_{i,j} = L_{i,j} R_i - R_j I_{i,j} = L_{i,j} R_i (I - U_{i,j}) - (I - P_{i,j}) R_j I_{i,j}, \quad \mathfrak{d}_{i,j}^* O_j \mathfrak{d}_{i,j} = G_i - G_j.$$

Here $\mathfrak{d}_{i,j} : (E, G_i) \rightarrow \mathcal{P}_j$ has the original theta image. Both terms on the right have the same remainder $I_{i,j}(I - U_{i,j}) : (E, G_i) \rightarrow (E, G_j)$: indeed $B_j L_{i,j} R_i = I_{i,j}$ and $B_j P_{i,j} R_j I_{i,j} = I_{i,j} U_{i,j}$. The full division primitive and theta image of their difference are supplied in the join. Reduction sends its labelled relation vector to the supported zero at that receiving label; the lifted map sends external τ to τ .

The arithmetic remainder estimate is extended to every admitted degree with its entire monic quotient formula. In the original notation of the upper-comparison chapter, it gives

$$G_{q-1} \preceq C_N G_N, \quad C_N = \frac{U_k(T) A_N^2 B_q(r)^2}{T a_k(T)}, \quad N \geq q-1,$$

with $T = Dq$, $r = kR_0/T < 1$, the unchanged original density mass, and all constants defined in the complete proof. Thus the actual endpoint gaps C_{2q-1}^{-1} and C_{2q}^{-1} are proved arithmetic inequalities. The exact ratio satisfies $C_{2q}/C_{2q-1} \leq 147/5 < 32$, so the same construction gives $\mathcal{B}_{h,k} \leq 2\mathcal{U}_k + q \log 32$ with $\mathcal{U}_k$ from R45. The same-source metric refinement now gives the stronger literal joint budget

$$\mathcal{B}_{h,k}^{\text{lo}} \leq \mathcal{B}_{h,k} \leq U_{h,k}^{\text{joint}} := \min\{q \log C_{2q-1} + q \log C_{2q}, \mathcal{B}_{h,k}^{\text{hi}}\}.$$

Equation (ERJ.32a) proves the required equality of the monic-source and monomial-source quotient kernels before taking this minimum. The complete five-estimate pointwise minimum and its nonlinear transport therefore apply to these exact original restriction returns. The two finite trace-certificate upper endpoints below may also be summed and included in the same minimum; their original entry errors and series tails remain attached to their actual matrices.

The finite matrix construction improves these directional bounds. For rational Hermitian enclosures of the actual kernels,

$$0 < L_i \preceq K_i \preceq U_i, \quad 0 < L_j \preceq K_j \preceq U_j,$$

define

$$g = (\text{Tr}(L_i^{-1} U_j) - q + 1)^{-1}, \quad r_* = 1 - g, \quad H_* = I - L_i U_j^{-1}, \quad t_m^* = \text{Tr}(H_*^m),$$

$$d = \text{Tr}(U_i L_j^{-1}) - \text{Tr}(L_i U_j^{-1}).$$

The complete ordered generalized-eigenvalue proof gives $0 < g \leq 1$, $d \geq 0$ and the rational intervals

$$\max\{0, t_m^* - m r_*^{m-1} d\} \leq \text{Tr}((I - U_{i,j})^m) \leq t_m^*.$$

The exact quotient-first triangular basis constructs these brackets from certified source and relation-coefficient intervals, retaining the actual polynomial rather than replacing it by an interval centre. For $r_* > 0$, summing the moment intervals and bounding the positive logarithmic tail gives a certificate for $\log(V_i/V_j)$ with width at most

$$\frac{d(1 - r_*^p)}{g} + \frac{q r_*^{p+1}}{(p+1)g}.$$

The source's sharper coefficient and a rational logarithm enclosure give the further proved refinement. At $g = 1$ the loss is exactly zero. Entry refinement followed by increasing p proves convergence at each fixed pair with every error term displayed.

The balanced central product of R44 now has a consequence for each of the two original endpoint pairs. Put $X = L_{h,k}/(C_h^{\text{bal}} q)$ and retain the full nonnegative phase/contraction penalty P_{mid} from the central product. Since $\text{rank}(K_{2q-1} - K_q) \leq q-1$, at least one central return eigenvalue is exactly one. The remaining $q-1$ eigenvalues have product at most $X^{-2(q-1)} e^{-P_{\text{mid}}}$. The ordered Rayleigh-quotient comparison with each endpoint therefore proves

$$\min \text{Spec } U_{q-1, 2q-1}, \quad \min \text{Spec } U_{q, 2q} \leq \min \left\{ 1, X^{-2} e^{-P_{\text{mid}}/(q-1)} \right\} \leq \min \left\{ 1, \frac{4(C_h^{\text{bal}})^2}{\delta^2 k^2} \right\}.$$

Every such eigenvalue is the squared norm fraction of the actual higher-degree minimum representative retained by the lower-degree source projection. The inverse return recovers its original coordinate, with precisely the relation correction proved above.

The whole inverse spectrum has the corresponding finite lower bound. To retain endomorphism types, write $U_{i,j} = T_{i,j}I_{i,j}$ on (E, G_i) , where $I_{i,j}$ is the original identity transport. Its coordinate matrix is $K_i G_j$. For every real $s > 0$, each endpoint pair separately obeys

$$\mathrm{Tr} U_{i,j}^{-s} \geq \max \left\{ q, 1 + (q-1)X^{2s}e^{sP_{\mathrm{mid}}/(q-1)} \right\}.$$

Indeed the central trace is one plus the inverse-power sum of its remaining $q-1$ eigenvalues. The tangent inequality $e^y \geq 1+y$ at their logarithmic mean bounds this sum from below by their geometric mean, and the ordered comparison transfers every eigenvalue. These same inverse observations also acquire the finite upper control proved in (ERJ.32b):

$$\mathrm{Tr} U_{q-1,2q-1}^{-s} + \mathrm{Tr} U_{q,2q}^{-s} \leq 2q-1 + e^{s\mathcal{B}_{h,k}} \leq 2q-1 + e^{sU_{h,k}^{\mathrm{joint}}}.$$

Indeed all $2q$ return eigenvalues $g_{a,j}$ lie in $(0, 1]$ and their negative logarithms sum exactly to $\mathcal{B}_{h,k}$. Writing $z_{a,j} = g_{a,j}^{-s} - 1 \geq 0$, expansion gives $\prod (1+z_{a,j}) \geq 1 + \sum z_{a,j}$, which is precisely the displayed bound. Each individual eigenvalue also satisfies $g_{a,j} \geq e^{-\mathcal{B}_{h,k}} \geq e^{-U_{h,k}^{\mathrm{joint}}}$. The original lower bounds and central unit eigenvalues above are retained simultaneously, with their full phase/contraction penalty.

If the exact central update rank is $\rho = \mathrm{rank}(K_{2q-1} - K_q) > 0$, put $A_+ = \max\{0, 2(q-1) \log X + P_{\mathrm{mid}}\}$. Retaining all $q - \rho$ unit returns gives the stronger bound

$$\mathrm{Tr} U_{i,j}^{-s} \geq q - \rho + \rho e^{sA_+/\rho}.$$

At $\rho = 0$ the central trace is exactly q and both endpoint traces are at least q . The complete proof and rank comparison are (ERJ.42)–(ERJ.42a). Under the canonical isometries the source restriction is the bijection $\mathcal{R} = \Pi_i|_{\ell_j E}$ between the two canonical images. Its inverse singular-value-power sum is exactly $\sum_a \sigma_a(\mathcal{R}^{-1})^{2s} = \mathrm{Tr} U_{i,j}^{-s}$ by (ERJ.11a). The ambient zero eigenspaces of the full projection products remain outside this restricted inverse and are retained by (ERJ.9).

Result R48: the complete arithmetic weight optimizer and a stronger moment family. For the original relation χ , coordinate $S = k/2 + iu$ and full raw-jet matrix E_q , put $\psi(u) = i^{-q}\chi(k/2 + iu)$, $Z = E_{q-1}$ and $\beta_j = b^{2j}/(2j)!$ for $0 < b < \pi/2$. The weight-optimization chapter proves the signed cofactor map

$$\det E_q[:, \{0, \dots, q\} \setminus \{j\}] = (-1)^{q-j} \psi_j \det Z, \quad \psi_j = \frac{i^{j-q}}{j!} \chi^{(j)}(k/2).$$

In particular every vanishing coefficient has its corresponding zero minor, with the full jet space retained. For auxiliary weights $\tau_j \geq 0$ of sum one, set

$$\eta_j = \frac{(2j)!}{(j!)^2 b^{2j}} |\chi^{(j)}(k/2)|^2, \quad D_\eta(\tau) = \sum_{j=0}^q \eta_j \prod_{l \neq j} \tau_l, \quad d(\eta) = \max_{\tau \geq 0, \sum \tau_j = 1} D_\eta(\tau).$$

Equations (OW.4)–(OW.13) prove the precise determinant identity

$$\det(E_q \mathrm{diag}(\tau_j \beta_j) E_q^*) = |\det Z|^2 \left(\prod_{j=0}^q \beta_j \right) D_\eta(\tau)$$

and its original phase-preserving congruence. The chapter proves every maximizer: a largest coefficient at least the sum of the others gives the corresponding zero weight and the remaining weights

$1/q$; exactly two equal positive coefficients give the explicit segment of maximizers. Otherwise the maximizer is unique and interior. Its zero-coefficient weights are $1/q$, and its positive-coefficient weights are $(1 - y_j)/q$, where

$$\sum_{\eta_j > 0} y_j = 1, \quad \eta_j = c_* y_j (1 - y_j), \quad 0 < y_j < 1.$$

The two monotone scalar constructions (OW.16)–(OW.19) determine the unique solution, including the branch with one large root. Equations (OW.21)–(OW.22a) prove the rational three-coefficient formula, coefficient-error bounds and terminating rational value certificates. The linear case $q = 1$ and all boundary cases are included in the same complete proof.

With the literal original $M_k = M_h(b)^k + M_h(-b)^k$ and comparator volume V_{2q-1}^ν from R45, the resulting arithmetic bound is

$$C_k \leq \mathcal{U}_{\text{opt}} = q \log M_k - \log \left(\prod_{j=0}^q \beta_j \right) - \log d(\eta) - \log V_{2q-1}^\nu.$$

The limit of the original positive raw-kernel inequality proves this bound at boundary optima; no reciprocal zero weight is used. For $\mathcal{U}_{\text{eq}}$ obtained from the same inequality with equal weights, (OW.23)–(OW.29) prove

$$0 \leq \mathcal{U}_{\text{eq}} - \mathcal{U}_{\text{opt}} = \log \frac{d(\eta)}{\sum_j \eta_j / (q+1)^q} \leq q \log(1 + 1/q) < 1.$$

Both non-strict inequalities are strict for the admitted complete quartet: its parity gives a zero coefficient, while its nonzero roots and monicity give at least two nonzero coefficients. Thus the finite optimization within this specified family is solved, and its improvement divided by $q_k \log k$ or q_k^2 tends to zero.

The continuation (OW.30)–(OW.40) proves a stronger source inequality. Write $\mu_{2j} = \int u^{2j} m_{h,k}(u) du$, retaining $\mu_0 = \mu_h^k$, and set $S_q(b) = \sum_{j=0}^q \beta_j \mu_{2j}$. Pointwise Cauchy–Schwarz and the full positive even exponential series, integrated against the original source, give

$$H_q \preceq S_q(b) \text{diag}(\beta_j^{-1}) \prec \frac{M_k}{2} \text{diag}(\beta_j^{-1}), \quad S_q(b) < M_k/2.$$

The corresponding upper expression $\mathcal{U}_{\text{cosh}}$ improves the earlier $\mathcal{U}_{\text{eq}}$ by exactly $q \log(2(q+1))$. Using $S_q(b)$ gives the further strict improvement $q \log(M_k/(2S_q(b)))$. Every constant follows from the integrated finite sum and both original Laplace values.

For every positive auxiliary list r_j , the same calculation proves

$$H_q \preceq \left(\sum_{j=0}^q r_j \mu_{2j} \right) \text{diag}(r_j^{-1}).$$

The exact positive-cone map $t_j = r_j \mu_{2j} / \sum_l r_l \mu_{2l}$, with inverse $r_j = s t_j / \mu_{2j}$, transforms its determinant optimization to the already solved polynomial D_κ , where $\kappa_j = |\psi_j|^2 \mu_{2j}$. Thus the entire stronger diagonal family has the proved optimum

$$C_k \leq \mathcal{U}_{\text{mom}} = \sum_{j=0}^q \log \mu_{2j} - \log d(\kappa) - \log V_{2q-1}^\nu.$$

All $q+1$ moment factors, every zero coefficient and the boundary raw-kernel limit are retained. The ray $r_j = \beta_j$ maps to $t_j^\beta = \beta_j \mu_{2j} / S_q(b)$, and the exact total gain is

$$\mathcal{U}_{\text{opt}} - \mathcal{U}_{\text{mom}} = q \log(2(q+1)) - \mathfrak{g}(\eta) + q \log \frac{M_k}{2S_q(b)} + \log \frac{d(\kappa)}{D_\kappa(t^\beta)}.$$

The last term is nonnegative and is evaluated by the same complete optimizer. The removed term $q_k \log(2(q_k + 1))$, divided by $q_k \log k$, tends to 2 for a simple quartet and to 3 for fixed common multiplicity greater than one.

Finally the original quotient-first source Gram proves $V_q = \det H_q / (\psi^* H_q \psi)$. Equation (OW.40) therefore calculates the exact remaining comparison loss against the full low-degree kernel:

$$\mathcal{U}_{\text{mom}} - (\log V_q - \log V_{2q-1}^\nu) = \sum_{j=0}^q \log \mu_{2j} - \log d(\kappa) - \log \det H_q + \log(\psi^* H_q \psi) \geq 0.$$

These identities retain all actual moments through degree $2q$. They determine the finite improvement and its precise comparison map without assigning an unproved growth rate to the last loss or the comparator determinant. The original source, support label and quotient action remain connected through the same cofactor and kernel maps.

Result R49: the first-degree phase product and each full block budget. The complete first-window chapter joins the original first-degree radius to the comparable-window theorem of PR 25, retaining the nonnegative generalized-eigenvalue correction. At $N = q - 1$, expand $\chi = p_q + \sum_{j < q} \gamma_j p_j$ and keep $\nu_0 = \|\chi\|^2 = \omega_q + \sum_{j < q} |\gamma_j|^2 \omega_j$. The rank-one update and the original phase identity give

$$\frac{V_q}{V_{q-1}} = \frac{\omega_q}{\nu_0}, \quad \gamma_{q-1} = -i\phi_{q-1}, \quad \epsilon_{q-1}^2 + \phi_{q-1}^2 = \frac{\nu_0 - \omega_q}{\omega_{q-1}}.$$

Equations (CJ.3)–(CJ.7) prove each equality in the actual source. For $\Lambda_N = \omega_N / V_N$, the first step consequently has exactly one contraction:

$$(\epsilon_{q-1}^2 + \phi_{q-1}^2) \Lambda_{q-1} = \Lambda_q (1 - \delta_q).$$

Multiplication by the regular consecutive identities gives the full first-window formula (CJ.9), for every $j \geq q$:

$$\prod_{N=q-1}^{j-1} (\epsilon_N^2 + \phi_N^2) = \frac{\omega_j V_{q-1}}{\omega_{q-1} V_j} (1 - \delta_j) \prod_{N=q}^{j-1} (1 - \delta_N)^2.$$

The original source contains no quotient inverse below degree $q - 1$. The complete two-sided monic norm envelope (CJ.15)–(CJ.18) supplies the explicit C_h^{win} for $n/2 \leq r \leq 2n$. For $D_h = \delta / (2C_h^{\text{win}})$ and each original block $(i, j) = (q - 1, 2q - 1)$ or $(q, 2q)$, it proves the finite bound

$$\log(V_i/V_j) \geq 2q \log(D_h k) + \mathcal{P}_{i,j} + \sum_{N=i}^{j-1} \log(1 + \phi_N^2 / L_{h,k}^2).$$

The penalties $\mathcal{P}_{i,j}$ are written completely in (CJ.13), including the single terminal factor for the first block and both boundary factors for the regular block. All terms added to the per-block $2q$ budget are nonnegative.

The original relation map in (CJ.20)–(CJ.21) has Gram $\Omega + F^* G_i F$ and is an isomorphism onto the whole newly admitted relation layer. At zero tilt and even tensor degree, the exact quartet's first increment matrix has a kernel by the full parity calculation. Every zero generalized eigenvalue stays in the q -dimensional cost spectrum, contributing the factor one to the determinant. For all $s > 0$, (CJ.22) also proves

$$\text{Tr } Q_{i,j}^{-s} \geq \max\{q, q(D_h k)^{2s}\}, \quad Q_{i,j} = T_{i,j} I_{i,j} \text{ on } (E, G_i).$$

These are traces of the same original metric endomorphism. The full cost, source relation, and its supported-zero quotient image remain connected by the maps in that chapter.

Result R50: the two relation traces and their actual comparison source. The complete relation-moment chapter proves the sharp finite determinant majorant from the two traces of the original positive cost operator $Z = (K_j - K_i)G_i$, keeping its full dimension and every zero eigenvalue. Writing $t_1 = \text{Tr } Z$, $t_2 = \text{Tr } Z^2$, for $q \geq 2$ define

$$d = \sqrt{\frac{qt_2 - t_1^2}{q-1}}, \quad a = \frac{t_1 + (q-1)d}{q}, \quad b = \frac{t_1 - d}{q}.$$

The complete rational Hermite remainder in that chapter gives

$$\log(V_i/V_j) = \log \det(I + Z) \leq \log(1 + a) + (q-1) \log(1 + b).$$

For dimension one the exact expression is $\log(1 + t_1)$, and for dimension zero it is zero. The proof identifies both traces with the original relation map and its exterior square, including every cross pairing. For the arithmetic upper kernel U_j , the positive space $\mathcal{C}_+ = (E^\vee / \ker(U_j - K_i), U_j - K_i)$ and its map $J_+[\alpha] = (U_j - K_i)\alpha$ realize the comparison cost $Z_+ = (U_j - K_i)G_i$. The constructed contraction from the original relation source has the complete positive defect

$$J_+(I - CC^\dagger)J_+^\dagger = (U_j - K_j)G_i.$$

This retains the precise map and the excess in the bound, together with the original arithmetic action defect and all unit return factors. The relation-moment chapter contains the full definitions and proofs.

Result R51: the constructed Deligne comparison maps and constituent coupling. The detailed Deligne sidebar proves the image, kernel and cone maps for the same compact-to-ordinary comparison, and the complementary degree duality with its actual boundary line. For every specified invariant $F \subseteq E$ and divisor depth $m \geq 1$, its original curve has the logarithmic complex

$$\mathcal{K}_{F,m} = [F\mathcal{O} + E\mathcal{O}(-m\infty) \xrightarrow{d} (F\mathcal{O} + E\mathcal{O}(-m\infty)) \otimes \Omega^1(\log \infty)].$$

Its complete cohomology is F in degree zero, $(E/F) \otimes \mathbb{T}$ in degree two and zero in degree one, with $\mathbb{T} = H^1(\Omega^1)$ and the retained trace $\text{tr}[dz/z] = 1$. The higher-depth quotient contracts by division by the displayed nonzero integer coefficients; its dual retains all meromorphic powers and the twist by $\mathcal{O}(-\infty)$. Each split lift distinguishes the represented kernel from external absence through their disjoint inclusions into the full kernel carrier.

The same original metric, $G(t) = G_j + t(G_i - G_j)$, gives the invariant quotient metric and coupling map proved in (DS53)–(DS65). With those specified maps, its endpoint identity is

$$\log(V_i/V_j) = \log \frac{\det G_F(1)}{\det G_F(0)} + \log \frac{\det Q_+}{\det Q_0} - \sum_{r=1}^{\infty} \frac{\text{Tr}(\Xi_F^r)}{r}.$$

The series has nonnegative terms before subtraction, and the sidebar proves its finite remainder. It also proves the exact original theta source defect $dK(z)H_t + r(z)Ia_t$, so the theta boundary and the retained constituent pass through their specified successive quotients. The two positive determinants can use R50 on their respective compressed matrices; the coupling subtraction remains in the same upper estimate.

Result R52: a degree-one exponential family with exact periods. For the original cyclic polynomial χ and its specified primitive Φ , the delivered exponential note proves

$$\mathcal{H} = \text{coker}(u\partial_S + \chi(S) - t), \quad \mathcal{H} \cong \mathbb{C}[u, t]^q, \quad \mathcal{H}/(u, t)\mathcal{H} \cong E, \quad (-u\nabla_t) \bmod (u, t) = A.$$

Its coefficient-module division, original theta observation, finite-rank source deformation, infinity chart and dual residue pairing are all retained with complete proofs in the exponential note and sidebar. The new determinant proof (XD1)–(XD26) computes the entire period determinant for the stated oriented rays:

$$\det \Pi(u, c, t) = \det \Pi^{\text{mon}}(u) \exp \left(\frac{\text{Tr } \Phi_t(A(t))}{u} \right).$$

All Gamma factors and monomial phases are given in (XD16)–(XD18). The proof uses the actual twisted-reduction matrices, keeps their off-diagonal corrections, and proves that their trace corrections vanish. It establishes nonvanishing across every repeated-root parameter. On the original canonical metric it gives

$$\log \det B_N^{\text{per}} = \log C_q(u) + 2 \operatorname{Re} \frac{\text{Tr } \Phi_t(A(t))}{u} - \log V_N.$$

Subtracting at the same parameters retains the exact original endpoint cost. The translation companion (DT1)–(DT13) further proves the complete maps under $\chi_a(S) = \chi(S - a)$: the coefficient action shifts by aI , the period gains the scalar $\exp[(-\Phi(-a) - ta)/u]$ and the full Pascal matrix, and the finite-field realization retains the character sheaf $\mathcal{L}_\psi((-\Phi(-a) - ta)/u)$ on the original (u, t) -base; its point restriction is the stated constant character line. The complete derived direct-image map and its projections are proved in (DT.14)–(DT.16). The original arithmetic fibre remains $a = 0$. These explicit maps preserve the canonical metric comparison and the full inherited endpoint inequalities.

The full connection in the same cyclic coefficient frame is now (XD.u1)–(XD.u7). Define its columns by the literal monic division

$$\Phi_t(S)S^b = (\chi(S) - t)Q_b^\Phi + R_b^\Phi, \quad (C_\chi(t))_b = R_b^\Phi, \quad (B_\chi)_b = (Q_b^\Phi)'. \quad (XD.u1)$$

The differential remainder is $R_b^\Phi - u(Q_b^\Phi)'$. With the original branch and all oriented contours retained,

$$\begin{aligned} \Omega_u &= -C_\chi(t)/u^2 + B_\chi/u, & \Pi_u &= \Pi\Omega_u, \\ \Omega_t &= -A(t)/u, & \Pi_t &= \Pi\Omega_t, \\ \partial_u \Omega_t - \partial_t \Omega_u + [\Omega_u, \Omega_t] &= 0. \end{aligned} \quad (XD.u2)$$

The degree-zero connection is $\partial_u - \Phi_t/u^2 + 1/u$; the degree-one connection is $\partial_u - \Phi_t/u^2$. Their cochain identity, complete division, and locally uniform contour differentiation are proved in (XD.u1)–(XD.u6). Here

$$C_\chi(t) = \Phi_t(A(t)), \quad (B_\chi)_{bb} = (b+1)/(q+1), \quad \partial_t B_\chi = 0, \quad \operatorname{Tr} B_\chi = q/2. \quad (XD.u3)$$

Thus the preceding determinant retains its full matrix connection, with the same original constant

$$K_q = (q+1)^{-q/2} e^{\pi i q/2} \det W \prod_{b=0}^{q-1} \Gamma((b+1)/(q+1)), \quad W_{jb} = e^{2\pi i j(b+1)/(q+1)} - 1. \quad (XD.u4)$$

On the exact primary slice $\chi = h = (s - \rho)^m$, $t = 0$, set $n = m + 1$, $c = -(-\rho)^n/n$, $\beta_b = (b+1)/n$ and $d_b = n^{\beta_b-1} e^{\pi i \beta_b} \Gamma(\beta_b)$. The original Pascal matrix has $P_{ab} = \binom{b}{a} \rho^{b-a}$ for $a \leq b$, and the ordered period matrix is exactly $\Pi_s = e^{c/u} W D(u) P$, where $D(u) = \operatorname{diag}(d_b u^{\beta_b})$. For an original p -dimensional ideal inclusion $I = J_{m-p} C_F$, whose J_{m-p} columns are $(s - \rho)^{m-p}, \dots, (s - \rho)^{m-1}$ in the unchanged s -basis, (SC.u5)–(SC.u7) compute

$$\det(I^* \Pi_s^* \Pi_s I) = |\det C_F|^2 n^p (p+1) e^{2p \operatorname{Re}(c/u)} \prod_{b=m-p}^{m-1} |d_b|^2 |u|^{2\beta_b}. \quad (XD.u5)$$

The full Gram is $e^{2\operatorname{Re}(c/u)} C_F^* D_{m-p}^* (W_{m-p}^* W_{m-p}) D_{m-p} C_F$, with $W_{m-p}^* W_{m-p} = n(I_p + \mathbf{1}\mathbf{1}^*)$. Its comparison with the original theta Gram divides the determinant by $\det(I^* G_N I)$, and uses $(I^* G_N I)^{-1}$ on that complete matrix. The proof retains the original source unit and every frame determinant. Its image plane is constant in u , so its normal u -map and u -curvature vanish on precisely this primary $t = 0$ slice. The general two-parameter normal map remains $N\Pi\Omega_a I$ for $a = u, t$, as in (SC.u1)–(SC.u4).

For AP's original packet polynomial h , full fixed Taylor representative ν , and fixed poles $p \in P_\nu$, the localized complex now has the entire connection (APU1)–(APU23). Put $f = \Phi_h - ts$ and

$$Q_p = \frac{f(s, t) - f(p, t)}{s - p} - \frac{h(s) - t}{\deg h + 1}.$$

Its ordinary quotient is the constant $1/(\deg h + 1)$, so its derivative correction is exactly zero. In AP6's original polynomial and simple-pole columns,

$$\Omega_u^{\text{loc}} = \begin{bmatrix} \Omega_u^{\text{pol}} & -Q/u^2 \\ 0 & -\operatorname{diag}(f(p, t))/u^2 \end{bmatrix}.$$

The weighted-residue matrix is $\mathcal{R} = [0, W_{\text{res}}]$, with $W_{\text{res}} = \operatorname{diag}(e^{f(p, t)/u})$; the positively oriented loop map is exactly $(2\pi i)\mathcal{R}$. Both maps are horizontal in u, t . The same complete ν intertwines these connections on the transported gauge frame, with target weight w/ν . The original endpoint-source map is $\sigma_h[\nu]J_0$, with every inverse Taylor coefficient retained, as proved in (APU18)–(APU22). Finally the original entire transport $C_a = \Pi_{\text{loc}}(u, t)^{-1}\Pi_{\text{loc}}(u, t + ua)$ has the exact derivative

$$(C_a)_u = -\Omega_u^{\text{loc}}(u, t)C_a + C_a(\Omega_u^{\text{loc}}(u, t + ua) + a\Omega_t^{\text{loc}}(u, t + ua)).$$

Its t -derivative and the differentiated weighted-residue and loop diagrams are proved in (APU23). The extra $a\Omega_t^{\text{loc}}$ is the derivative of the original parameter shift. The identification $h = \chi_{h,1}$ is the literal variable isomorphism (PC4); at higher tensor degree the cyclic and product families retain their specified η_k and source maps rather than being assigned a common coefficient rank.

Result R53: the residue trace and the complete collision map. For the unchanged monic polynomial $H(S) = \chi(S) - t$, the complete SGA trace chapter constructs the perfect residue functional $\lambda_t[P] = [S^{q-1}] \operatorname{rem}_H P$ and the actual diagonal coevaluation

$$C_H(X, Y) = \frac{H(X) - H(Y)}{X - Y}, \quad \operatorname{Tr}_{E_t/R[t]} M_P = \lambda_t(\chi' P).$$

The fraction is a polynomial, its multiplication image is χ' , and the chapter proves the inverse pairing identities without dividing by a discriminant. The original logarithmic source relation maps to $[\chi' P]_\chi$ before this trace is taken. Its complete periodic diagonal resolution retains both odd and positive even degrees.

The new comparison (SC26)–(SC30) proves the precise specialization of those degrees. Over $T = \mathbb{C}[t]$, put $\mathcal{E} = T[S]/(\chi - t)$ and $M = \mathcal{E}/\chi'\mathcal{E}$. The isomorphism $\mathcal{E} \simeq \mathbb{C}[S]$, with $t \mapsto \chi(S)$, makes $0 \rightarrow \mathcal{E} \xrightarrow{\chi'} \mathcal{E} \rightarrow M \rightarrow 0$ a free T -resolution. For $\kappa = \mathbb{C}[t]/(t - t_0)$,

$$\operatorname{Tor}_1^T(M, \kappa) \xrightarrow{\sim} \operatorname{ann}_{E_{t_0}}(\chi'), \quad [v]_{\chi'} \mapsto [w]_{\chi - t_0}, \quad (\chi - t_0)v = \chi'w.$$

The proof gives both inverse directions and the exact S -action. Thus every positive even group of the family is zero, while the positive even groups at a collision are these explicit Tor modules; the odd groups are $M \otimes_T \kappa$. Each length- m local factor retains both $m - 1$ -dimensional modules and their nilpotent actions. The Gamma calculation also evaluates the entire period Gram determinant as

$$\det(\Pi^* \Pi) = (2\pi|u|)^q \exp\left(2 \operatorname{Re} \frac{\operatorname{Tr} \Phi_t(A + t\mathcal{R})}{u}\right),$$

with the complete phase-containing determinant still given by R52.

Result R54: exact constituent curvature and neighboring volumes. For an actual invariant injection $I : F \hookrightarrow E$, $0 < p = \dim F < q$, put $\ell[P] = [S^{q-1}] \operatorname{rem}_\chi P$, $\mathcal{R} = e_0 \ell$, $L = \ell I$, $Y = \Pi I$, $H = Y^* Y$, $N = 1 - Y H^{-1} Y^*$, and $z = N \Pi e_0$. The complete proof (SC9)–(SC25) identifies the invariant image with the unchanged polynomial ideal $(g)/(\chi)$, proves $L \neq 0$ and $z(t) \neq 0$ for every parameter, and computes

$$N Y' = -\frac{t}{u} z L, \quad \partial_{\bar{t}} \partial_t \log \det H = \frac{|t|^2}{|u|^2} \|z\|^2 L H^{-1} L^*.$$

The normal derivative has rank one at every nonzero parameter; the normal acceleration has rank one at zero. The curvature vanishes precisely quadratically at zero and is positive elsewhere. Its factorization through the original section $r_{N e_0} L$, quotient j_E , and period observation $N \Pi$ retains the source kernel and its supported zero.

For the literal polynomial frames $J_g = [g, Sg, \dots, S^{p-1}g]$, its prefix J_- , and $J_+ = [J_g, e_0]$, put $h_J = \det(J^* \Pi^* \Pi J)$. The full frame map, Schur-complement and cofactor proof in (SC31)–(SC37) gives

$$\partial_{\bar{t}} \partial_t \log h_g = \frac{|t|^2 h_+ h_-}{|u|^2 h_g^2}.$$

Each volume factors exactly as $h_J = v_{N,J} b_{N,J}$, where $v_{N,J} = \det(J^* G_N J)$ retains the original theta metric and $b_{N,J}$ is its specified period-comparison determinant. The empty prefix has determinant one. In codimension one, $\det J_+ = (-1)^{q-1}$, so h_+ is the full explicitly evaluated period determinant above. These are the exact maps and weights joining this curvature to the neighboring-volume calculation.

Result R55: the retained Hochschild and critical-line comparisons. The complete Connes–Consani comparison proves the actual restricted factorization

$$V \xrightarrow{j} j(V) \xrightarrow{\operatorname{Tr}} \mathcal{B}, \quad \operatorname{Tr} j = \Theta, \quad \mathcal{E} = \frac{1}{2} \mathcal{U} \Theta, \quad (D^2 - D) e^{-\pi u^2} = \phi_*.$$

The half-density map $\mathcal{U} F = u^{1/2} F$ is the specified half-line isometry. The cochain isomorphism uses the complete two-moment source and the Laplacian’s continuous inverse. The critical-line map $\Gamma : Q \rightarrow Q_{\text{crit}}$ has, on each original finite packet, the exact kernel $\ker(\Gamma \sigma_Z) = E_{Z, \text{off}}$, including every generalized block. The critical recovery is the explicit jet

$$\Xi_\rho[f] = \sum_{j=0}^{m-1} \frac{i^{-j}}{j!} f^{(j)}(\gamma) \epsilon^j, \quad \rho = \frac{1}{2} + i\gamma.$$

The full note proves the reciprocal multiplier argument, the recovery composite and the supported image of every killed vector.

The raw circle zero mode is retained as a separate smooth coordinate; the specified Gaussian average of the original theta seed proves that this line is in the closed source-generated module. Its exact local flat-seminorm estimate and the printed large-circle limit correction remain with that proof. Finally the original-metric Laplacian identities

$$\mathbb{L}_k^* G - G \mathbb{L}_k = A^* W_k - W_k A, \quad G \mathbb{L}_k = W_k A - A^* G A$$

and their complete numerical-range argument are retained with the actual metric control parameter. Neither the trace construction, the finite-kernel calculation, nor the period determinant supplies an unproved uniform bound for that parameter.

Result R56: the actual critical-comparison kernel through periods and tensors. The full proof (PC1)–(PC41) identifies the single-packet polynomial $\chi_{h,1} = h$ by its explicit variable isomorphism $\iota_1 : [P(S)] \mapsto [P(s)]$. The original arithmetic inclusion is $\eta_h = M_{v_h} \iota_1$, with $v_h = j_h(2\xi/h)$ and every inverse jet coefficient retained. It proves

$$J_h r_N = \eta_h, \quad j_E = \eta_h^{-1} J_h, \quad j_E r_N = I, \quad q r_N = \sigma_h \eta_h.$$

The critical comparison is consequently the actual weighted map $\mathcal{C}_h = \Gamma \sigma_h \eta_h$; its kernel is the full off-critical primary summand. Each surviving critical jet is recovered with the original $i^{-j}/j!$ factor and the inverse of the displayed local arithmetic unit.

For every original integer tensor degree $k \geq 1$, retain $E_k = \mathbb{C}[S]/(\chi_{h,k})$, its actual weighted inclusion η_k , and the factorwise completed-projective comparison

$$\mathcal{C}_k = \Gamma^{\widehat{\otimes} k} \sigma_h^{\widehat{\otimes} k} \eta_k.$$

Let $\chi_{c,k}$ be the monic sum polynomial obtained from the all-critical tuples, with the complete maximum nilpotent length at each literally equal sum; for no critical factors set it to 1. The full proof constructs the variable isomorphism on the tensor carriers, preserves the original unit, and gives a continuous jet retraction proving that the finite image survives completion. It yields

$$\ker \mathcal{C}_k = (\chi_{c,k})/(\chi_{h,k}).$$

At a sum λ with full multiplicity m_λ and critical-tuple multiplicity r_λ , its exact local kernel is the image of $[b] \mapsto [x^{r_\lambda} a_\lambda(x)b]$ from $\mathbb{C}[x]/(x^{m_\lambda - r_\lambda})$, where $x = S - \lambda$ and the local unit in $\chi_{c,k}$ is retained. This includes the additional jets when different tuples share a sum.

For the period matrix of this same original polynomial, $\mathcal{C}_{k,t} = \mathcal{C}_k \Pi_k^{-1}$ has kernel $\Pi_k \ker \mathcal{C}_k$. Its exact sum-action defect is

$$\mathcal{C}_{k,t} A_{k,t}^{\text{per}} - M^{[k]} \mathcal{C}_{k,t} = t \mathcal{C}_k(e_{0,k}) \ell_k \Pi_k^{-1}.$$

For a proper nonzero kernel it has the proved rank-one restriction, with kernel $\Pi_k(\ker \mathcal{C}_k \cap \ker \ell_k)$. The curvature and neighboring-minor identities in R54 therefore measure this actual critical-comparison kernel. The original theta metric is connected by the complete congruence and derivative cancellation. All-critical and no-critical packets retain their different empty and full kernels, even though both endpoint curvatures vanish.

The same weighted observer now has its full singular-parameter equation (PC.u1)–(PC.u3):

$$\mathcal{C}_{k,u,t} = \mathcal{C}_k \Pi_\chi(u, t)^{-1}, \quad \partial_u \mathcal{C}_{k,u,t} = \mathcal{C}_k (C_\chi(t)/u^2 - B_\chi/u) \Pi_\chi^{-1}, \quad \ker \mathcal{C}_{k,u,t} = \Pi_\chi \ker \mathcal{C}_k.$$

Here the polynomial is literally $\chi = \chi_{h,k}$; the product-period restriction on $E_h^{\otimes k}$ is instead the actual rectangular form $\eta_k^* \Pi_{\text{prod}}^* \Pi_{\text{prod}} \eta_k$. The source identity and parameter cyclic relation following (XD.u7) are the exact maps between those two domains. For the original kernel inclusion I_k , its complete normal maps are $Z_a = N \Pi_\chi \Omega_a I_k$, $a = u, t$, and all four curvature coefficients are

$$\partial_a \partial_b \log \det H = \text{Tr}(H^{-1} Z_a^* Z_b).$$

At $t = 0$, the order-two coefficient preserves this ideal, so $Z_u = u^{-1} N \Pi_\chi B_\chi I_k$, $Z_t = 0$. These are calculated matrix entries on the same kernel; neither the full ideal nor its nilpotent jets have been suppressed.

The actual tensor coefficient map is also now retained in (PC30a)–(PC30g). On an ordered local tuple let $x_i = s_i - \rho_i$, $\lambda = \sum_i \rho_i$, $D = \sum_i (m_i - 1)$, and $U_\rho = \prod_i j_{\rho_i}(v_h)$. Over the specified coefficient localization $\mathcal{R} = A_{\ker \alpha}$, for an actual map to characteristic $p > \max_i m_i$, the exact map and its saturation basis are

$$V_j = \sum_{\substack{0 \leq b_i < m_i \\ |\mathbf{b}|=j}} \frac{x^{\mathbf{b}}}{\prod_i b_i!}, \quad W_j = U_\rho V_j, \quad \eta_\rho((S - \lambda)^j) = j! W_j, \quad \Lambda_U = \bigoplus_{j=0}^D \mathcal{R} W_j.$$

Its full containing tensor module retains the explicitly split free complement, and

$$\Lambda_U/\eta_\rho \mathcal{C}_{\mathcal{R}} \simeq \bigoplus_{j=0}^D \mathcal{R}/(p^{v_p(j!)}), \quad \ker \bar{\eta}_\rho = ((S - \bar{\lambda})^p), \quad \text{im } \bar{\eta}_\rho = \bigoplus_{j=0}^{\min(D, p-1)} B\bar{W}_j.$$

Here B is the specified target k_0 , or the explicit quotient $\mathcal{R}/p\mathcal{R}$. The kernel is zero when $D < p$. The original source index is $D + 1$, while the index on the actual specialized image is $\min(p, D + 1)$; the full free resolution and Tor connecting map in (PC30e) prove their exact relation. When the specified map includes all one-factor CRT data and $p > m_\rho$ for every retained primary order, (PC30f)–(PC30g) also retain every new residual collision:

$$\psi_{h,k}(X) = \prod_{\mu} (X - \mu)^{\max_{\alpha}(\sum_i \rho_i) = \mu \min(p, 1 + \sum_i (m_i - 1))},$$

$$\ker \bar{\eta}_k = (\psi_{h,k})/(\bar{\chi}_{h,k}), \quad \text{im } \bar{\eta}_k \simeq k_0[X]/(\psi_{h,k}).$$

The product is over attained residual sums; if the carrier is empty, its product is 1 and both modules are zero. The last arrow is the proved module map $[P] \mapsto \bar{U}_k P(\bar{S})$; its unweighted counterpart is the corresponding algebra map.

For the complete primary packet at $t_i = 0$, the ordered product boundary is explicitly calculated in (SPBT.1)–(SPBT.3), (BPC.1)–(BPC.14), (BTP.1)–(BTP.11), and (BTF.1)–(BTF.11). Writing $n = m + 1$, its ordinary complex invariant dimension is

$$d_{0,k} = \frac{m^k + m(-1)^k}{m + 1}.$$

With E_0 selecting $\sum_i (b_i + 1) \equiv 0 \pmod{n}$, the exact coefficient, source and period projectors satisfy

$$Q_0 = P_k^{-1} E_0 P_k, \quad \hat{Q}_0 = U_k Q_0 U_k^{-1}, \quad \mathcal{P}_0 \Pi_{\text{prod}} U_k^{-1} = \Pi_{\text{prod}} U_k^{-1} \hat{Q}_0.$$

The terminal original monomial survives precisely when $n \mid k$, and retains its arithmetic eigenvalue $a^{k\rho}$. The exact compression and its outgoing nilpotent map are (BTP.7)–(BTP.8). On the actual phase specialization with $p > m + 1$, the common additive factor remains $\mathcal{L}_\psi(kc/u)$: the invariant dimension is $d_{0,k}$ when $kc = 0$ and zero otherwise, and the Swan conductor is respectively zero or m^k . Every surviving boundary orbit retains its full product of negative Gauss constants and weight k . The common cyclotomic projector maps in (BTF.6) give their exact two base changes; they do not assign a characteristic- p coefficient scalar to a characteristic-zero Gauss line. The amplified coefficient still contains its original $K!$, $K = k(m - 1)$, with image zero exactly when $K \geq p$ on a coefficient stage retaining the inverse unit. The case $m = 1$ has $K = 0$ and no factorial loss. Moreover, in the retained off-critical quartet CRT corner for $k \geq p$, (BTF.9) proves

$$1 = p(\rho + \bar{\rho} - 1)\mathcal{D}, \quad p^{-1} = (\rho + \bar{\rho} - 1)\mathcal{D}$$

from the actual separating idempotent's divided difference. That larger stage has no unital characteristic- p map; the original local coefficient map, its precise saturation, kernel, Tor class and character remain as displayed above.

Result R57: computed Laplacian control and its curvature comparison. The full original-metric calculation (LC1)–(LC16) uses $A_t = A + tR$, $R = e_0 \ell$, and $W_t = A_t^* G_N + G_N A_t - kG_N$. For $q > 1$, $\ell e_0 = 0$, so $R^2 = 0$. The two actual G_N -orthogonal columns $e_0, G_N^{-1} \ell^*$ give the exact additional control spectrum

$$\text{spec}_{\neq 0}(G_N^{-1}(W_t - W_0)) = \{|t|\sigma_N, -|t|\sigma_N\}, \quad \sigma_N^2 = (e_0^* G_N e_0)(\ell G_N^{-1} \ell^*),$$

when $t \neq 0$. For $q = 1$ the same difference is exactly $2 \operatorname{Re} t$ times identity. For the retained reflection-stable packet, the complete earlier source-minor calculation evaluates $\epsilon_N^2 = \alpha_{N+1} \Delta_N / \det K_N$, so the actual quantity

$$E_N(t) = \epsilon_N + \begin{cases} |t| \sigma_N, & q > 1, \\ 2|\operatorname{Re} t|, & q = 1 \end{cases}$$

bounds the control on the same metric. With this computed value, every point z of the original-metric numerical range of $A_t^2 - kA_t$ satisfies

$$\operatorname{Re} z \leq \frac{E_N(t)^2 - k^2}{4}, \quad (\operatorname{Im} z)^2 \leq E_N(t)^2 \left(\frac{E_N(t)^2 - k^2}{4} - \operatorname{Re} z \right).$$

The proof retains every original input vector in homogeneous coordinates and transports the complete inequality through Π with metric $\Pi^{-*} G_N \Pi^{-1}$.

The same source factors also control the calculated constituent curvature. For its actual G_N -projection P_F , set $a_\perp = \|(I - P_F)e_0\|_{G_N}^2$ and $b_F = \|P_F G_N^{-1} \ell^*\|_{G_N}^2$. Let $m(t), M(t)$ be the actual least and greatest eigenvalues of $G_N^{-1} \Pi^* \Pi$. Its positive curvature coefficient obeys

$$\frac{m(t)}{M(t)} \frac{a_\perp b_F}{|u|^2} \leq c_F(t) \leq \frac{M(t)}{m(t)} \frac{a_\perp b_F}{|u|^2} \leq \frac{M(t)}{m(t)} \frac{\sigma_N^2}{|u|^2}.$$

The complete proof supplies the exact nonnegative projection losses between $a_\perp b_F$ and σ_N^2 . These statements retain the actual period-comparison eigenvalues and original theta masses; no uniform packet-size bound is inserted.

The same numerical-range calculation is now transported in both original parameters by (LC.u1), with the unchanged $E_N(t)$ and G_N :

$$\begin{aligned} \partial_u \tilde{G}_N &= -\Pi^{-*} G_N \Omega_u \Pi^{-1}, & \partial_{\bar{u}} \tilde{G}_N &= -\Pi^{-*} \Omega_u^* G_N \Pi^{-1}, \\ \partial_u \tilde{L}_t &= \Pi[\Omega_u, L_t] \Pi^{-1}, & \partial_u \tilde{A}_t &= \Pi[\Omega_u, A_t] \Pi^{-1}. \end{aligned}$$

Here $\Omega_u = -C_\chi(t)/u^2 + B_\chi/u$ is the full original cyclic connection. The exact original source commutator retains $r_N[A, \Omega_u]j_E + dK_N^{\text{prim}} \Omega_u j_E$, as proved in (DS74) and carried through (LC.u1). Thus the preceding original-metric parabola holds for every retained $u \neq 0$, with its same control value and the displayed moving metric, rather than an uncomputed target norm. The comparison numbers in (LC14)–(LC16) are now the actual $m(u, t), M(u, t)$ of $G_N^{-1} \Pi(u, t)^* \Pi(u, t)$. For each constituent and each neighboring inclusion, (SC.u1)–(SC.u4) give the complete Hermitian Hessian $\operatorname{Tr}(H^{-1} Z_a^* Z_b)$; at nonzero t , both terms of Ω_u and their cross pairing remain. On the precise single-primary ideal slice the full matrix and ideal determinant are evaluated by (SC.u5)–(SC.u7), including the original comparison Gram.

Result R58: the original arithmetic quotient from a finite circle. The complete periodized-source proof (P1)–(P64), together with the full source calculations (PSA1)–(PSA29) and (PSD1)–(PSD41), retains $v_h = 2\xi/h, w_h(t) = |v_h(1/2 + it)|^2/(2\pi)$ and $m_{h,k} = w_h^{*k}$. Its logarithmic coordinate map keeps the density $e^{kr + \sum z_i}$ and the ordered-coordinate orientation $(-1)^{k-1}$. The scalar circle sequence is related to the actual relative Hilbert fibre by Fourier coefficients $L^{-1/2} a_n \widehat{\mathcal{U}_k F_h^{\otimes k}}(2\pi n/L)$, whose squared norm is $\sum_n \nu_n |a_n|^2$ with $\nu_n = (2\pi/L) m_{h,k}(2\pi n/L)$. The zero mode remains in this sum.

For the original degree- N polynomial Gram M_N and unchanged remainder map J_N , define the actual finite sampled Gram $M_N(L, J)$ by retaining $|n| \leq J$. The explicit original-source quantities in (FC3)–(FC3a) produce $\alpha = 1 - \eta_P - \eta_T > 0$ and $\beta = 1 + \eta_P$, and prove

$$\alpha M_N \preceq M_N(L, J) \preceq \beta M_N, \quad \alpha G_N \preceq G_N(L, J) \preceq \beta G_N, \quad G_N = (J_N M_N^{-1} J_N^*)^{-1}.$$

The second assertion follows by taking minima over the same original remainder fibres. The two minimizing representatives retain their explicit difference in $\chi\mathcal{P}_{N-q}$ and its complete theta primitive. On the common degree $D = 2q + 2$, all four endpoint degrees and both generator raises are covered. On the literal common source $\mathcal{H} = \mathcal{P}_{2q}$, restrict those degree- D forms to $M^{(0)} = M_{2q}$ and $M^{(1)} = M_{2q}(L, J)$. The full signed derivation (PSA24a)–(PSA25) now gives the propagated error at the original claim site:

$$\begin{aligned} |\mathcal{B}_{h,k}(L, J) - \mathcal{B}_{h,k}| &\leq \mathcal{J}_{L,J}^{(5)} \leq \mathcal{J}_{L,J} \\ &\leq \log \frac{b_{q+2}}{b_q} + 2 \sum_{j=1}^{q-1} \log \frac{b_{2q+2-j}}{b_j} \leq (2q-1) \log(\beta/\alpha). \end{aligned}$$

Here $b_1 \leq \dots \leq b_{2q+1}$ are the eigenvalues of $D_{L,J} = (M^{(0)})^{-1}M^{(1)}$, all in $[\alpha, \beta]$. For $M(x) = (1-x)M^{(0)} + xM^{(1)}$, let P_N, Q_N be its orthogonal projections onto $\mathcal{P}_N$ and $\chi\mathcal{P}_{N-q}$ inside $\mathcal{H}$, and put $U = Q_{2q-1} + Q_{2q} - Q_q$, $W = P_{2q-1} - P_{q-1} + P_{2q} - P_q$. Then the actual signed derivative is $\text{Tr}((U-W)M(x)^{-1}(M^{(1)} - M^{(0)}))$. Writing $c_j(x) = (b_j - 1)/(1 - x + xb_j)$, $d(x) = c_{2q+1}(x) - c_1(x)$ and $s(x) = \dim(\text{ran } U \cap \text{ran } W)$, the retained full control is

$$\begin{aligned} \mathcal{J}_{L,J} &= \int_0^1 \min \left\{ c_{q+2} - c_q + 2 \sum_{j=1}^{q-1} (c_{2q+2-j} - c_j), \right. \\ &\quad \left. \frac{d(x)}{2} \min \{ 4q - 2s(x), \sqrt{(2q+1)(8q-4-2\text{Tr}(UW))} \} \right\} dx. \end{aligned}$$

For the actual positive atomic moment measure in this construction, put $C(x) = M(x)^{-1}(M^{(1)} - M^{(0)})$, the exact metric derivative already displayed. The complete five-entry bound in (PSA24f)–(PSA24g) additionally retains the exact trace term $S_{\text{tr}}(x) = d(x)\|U - W\|_1/2$, the centered Hilbert-Schmidt term $S_{\text{HS}}(x) = \sqrt{(\text{Tr } C^2 - (\text{Tr } C)^2/(2q+1)) \text{Tr}((U-W)^2)}$, and the original-angle term $(2q-1)\sqrt{1 - e^{-\mathcal{B}(x)/(2q-1)}}d(x)$. Thus $\mathcal{J}_{L,J}^{(5)}$ is the integral of the minimum of these three functions and the two original functions in $\mathcal{J}_{L,J}$. All five bound the same signed derivative. Strict $\mathcal{B}(x) > 0$ is proved on this actual moment measure by the reflected polynomial $\chi^{\#_k}$ and positivity of its Gram. The constructed finite Neumann control in (PSA25ba)–(PSA25bc) also gives $j_{\ell_N} - e_{\ell_N} \leq \mathcal{B}(L, J) - \mathcal{B} \leq j_{\ell_N} + e_{\ell_N}$, with the complete finite matrix center and $e_{\ell_N} \leq \vartheta^{\ell_N+1} \sqrt{K_{D_{L,J}}(8q-6)} \rightarrow 0$ on this fixed original pair of forms. Let $a_q = 2q - 1$ and $H_0 = 2 \text{arcosh}(e^{\mathcal{B}/(2a_q)})$. The five-entry nonlinear radius $\mathcal{I}_{L,J}$ is proved in (PSA24f) and includes all four linear-control numerators divided by $a_q \sqrt{1 - e^{-\mathcal{B}(x)/a_q}}$. Consequently the earlier finite-circle endpoint now has the full simultaneous enclosure

$$\begin{aligned} \mathcal{B}(L, J) &\geq \max \left\{ 0, \mathcal{B} - \mathcal{J}_{L,J}^{(5)}, 2a_q \log \cosh \frac{\max\{0, H_0 - \mathcal{I}_{L,J}\}}{2}, \mathcal{B} + j_{\ell_N} - e_{\ell_N} \right\}, \\ \mathcal{B}(L, J) &\leq \min \left\{ \mathcal{B} + \mathcal{J}_{L,J}^{(5)}, 2a_q \log \cosh \frac{H_0 + \mathcal{I}_{L,J}}{2}, \mathcal{B} + j_{\ell_N} + e_{\ell_N} \right\}. \end{aligned}$$

This is precisely (PSA25a) and (FC13b), with the unchanged continuous and positive atomic measures explicitly identified. The exact signed center retains its integration error in any numerical evaluation. The complete proof at (PSA24a)–(PSA25a) establishes these source maps, ranks $q + 1$, traces $2q$, and the exact metric comparison, including the common-range and cross-trace terms. Its endpoint substitution is also made in (FC13a). The two generator raises still use the original degree $D = 2q + 2$. At fixed positive error budgets this is $O(q_k)$; its ratio to $q_k \log k$ tends to zero. The required L, J are explicit functions of the original weighted and derivative Grams. Their growth and the arithmetic sample enclosures are retained as actual quantities, rather than replaced by unproved uniform estimates.

Result R59: the joint critical-jet and circle observation. The full density proof obtains the original exponential tails from the gamma ray integral and the alternating Dirichlet series, including every canceled value $v_h(\rho) = g^{(m)}(\rho)/h^{(m)}(\rho) \neq 0$. It proves density on the required analytic strip, with its Cauchy-Schwarz half-width retained, and computes the completed circle quotient exactly. If $b = p_L$ is the squarefree product of the sampled roots of $\chi = \chi_{h,k}$, then

$$\ker \theta_L = (b)/(\chi), \quad G_N(L) \downarrow G_\infty(L), \quad \text{rad } G_\infty(L) = (b)/(\chi).$$

For $k \geq 2$ the complete difference $G_N(L) - G_\infty(L)$ is positive definite at every finite admitted degree: a nonzero minimizing polynomial cannot vanish on the infinite complement of the selected sample atoms. The limiting kernel retains the full unsampled primary blocks and all nonconstant jets at sampled roots.

The proof (DC1)–(DC30) compares this with the actual weighted tensor-critical map C_k , whose kernel is $(a)/(\chi)$ for $a = \chi_{c,k}$. Put $d = \gcd(a, b)$ and $l = \text{lcm}(a, b)$. Using the complete critical inverse jets and the original weighted circle coordinates gives

$$\text{im}(C_k, \theta_L) \simeq \text{im } C_k \times_{\mathbb{C}[S]/(d)} \text{im } \theta_L \simeq \mathbb{C}[S]/(l).$$

The joint kernel is $(l)/(\chi)$ and the common quotient is $\mathbb{C}[S]/(d)$. At each original sum root, their quotient lengths are respectively the maximum and minimum of the critical cyclic length and the sampled length in $\{0, 1\}$; all local unit cofactors are retained in the kernel inclusions. A factorization $\theta_L = TC_k$ exists exactly when $b \mid a$, with its explicit inverse-unit and reduction formula. The reverse factorization exists exactly when $a \mid b$. At $k = 1$, full-order cancellation proves that every sampled selected root has positive weight and $b \mid a$. For general tensor degree, the extra circle summand has defining polynomial b/d and the explicit original polynomial source lift in (DC29). Its existence criterion asserts no existence of an off-critical zero.

All four observations transport through the same original period matrix. For the role $s \in \{a, b, d, l\}$, retain its actual map T_s and multiplier M_s . Then

$$T_{s,t} = T_s \Pi^{-1}, \quad u \partial_t T_{s,t} - M_s T_{s,t} = t T_s(e_0) \ell \Pi^{-1}.$$

Their kernels, intersection, sum, crossed observations and complete rank-one action defects are calculated in (DC23)–(DC30). Their Split-Zero lifts retain each support and its receiving supported zero.

The entire same diamond now has its exact u -equation (DC31), for all four formal roles $s \in \{a, b, d, l\}$:

$$T_{s,u,t} = T_s \Pi(u, t)^{-1}, \quad \partial_u T_{s,u,t} = T_s (C_\chi(t)/u^2 - B_\chi/u) \Pi(u, t)^{-1}.$$

Its kernels are ΠK_s , and its specified right inverses, intersection and sum diagrams are the same ones in (DC23)–(DC30). Multiplication by the original common quotient maps proves their differential compatibility, retaining all four roles and every inverse-unit factor. For the actual circle weights put $D_\nu = \text{diag}(\nu_n)_{n \in \mathcal{Z}_L}$. The exact observed form and its derivatives are (DC32):

$$\begin{aligned} H_b^{\text{obs}} &= \Pi^{-*} T_b^* D_\nu T_b \Pi^{-1}, & \ker H_b^{\text{obs}} &= \Pi K_b, \\ \partial_u H_b^{\text{obs}} &= -\Pi^{-*} T_b^* D_\nu T_b \Omega_u \Pi^{-1}, & \partial_u H_b^{\text{obs}} &= -\Pi^{-*} \Omega_u^* T_b^* D_\nu T_b \Pi^{-1}. \end{aligned}$$

Every retained atom has its original positive weight; an empty sample set gives the empty observation and its full kernel. The shared and additional circle sums, polynomial source lift and receiving support labels therefore retain their original maps while the parameter varies.

Result R60: universal residue endomorphisms and metric variation. The full calculation (RCX1)–(RCX40) extends the residue insertion $R = e_0 \ell$ over every commutative coefficient ring B

with monic χ . With the original residue matrix $\mathcal{B}_{ij} = \ell(S^{i+j})$, its determinant remains $(-1)^{q(q-1)/2}$. Every coefficient endomorphism has the exact inverse expansion

$$T = \sum_{i,j} (T\mathcal{B}^{-1})_{ij} A^i R A^j.$$

The full proof gives matrix units, their multiplication and base change. Their original source lifts $r_N T j_E$ form an injective representation in the corner with identity $r_N j_E$ and kill the same original theta boundaries.

For a proper nonzero invariant constituent $I : F \hookrightarrow E$, retain the residual $r_M = (1 - P_M)e_0$ and the residue-dual vector $w_M = I(I^* M I)^{-1}(\ell I)^*$. They are M -orthogonal, with squared norms $q_M, d_M > 0$, and $\mathfrak{c}_F(M) = q_M d_M$. Along any actual differentiable positive-form path,

$$\frac{d}{ds} \log \mathfrak{c}_F(M) = \text{Tr} \left[\left(\frac{r_M r_M^* M}{q_M} - \frac{w_M w_M^* M}{d_M} \right) M^{-1} \dot{M} \right].$$

The parenthesized operator has eigenvalues $1, -1, 0$ with the stated multiplicities, yielding the exact spectral-spread bound. For the original endpoint forms $G_i \succeq G_j$, with extreme relative eigenvalues $0 < \theta \leq \eta \leq 1$, this proves

$$\left| \log \frac{\mathfrak{c}_F(G_j)}{\mathfrak{c}_F(G_i)} \right| \leq \log(\eta/\theta) \leq -\log \theta \leq \log \frac{\det G_i}{\det G_j}.$$

The complete neighboring-minor formula $\mathfrak{c}_F(M) = v_{J_+}(M) v_{J_-}(M) / v_{J_g}(M)^2$ retains every original frame determinant and both constituent dimensions. The finite sampling comparison from R58 gives the dimension-free coefficient interval $\alpha/\beta \leq \mathfrak{c}_F(G_N(L, J)) / \mathfrak{c}_F(G_N) \leq \beta/\alpha$.

Result R61: sampled control with its exact commutator error. The full proof (FC1)–(FC29), including (FC3a), keeps the two actual forms $G = G_N, H = G_N(L, J)$, the original $T_t = A + tR - k/2$, and $B = G^{-1}(H - G)$. It first proves

$$(I + B)X_H = X_G + T_t^{\dagger G} B + B T_t, \quad X_G = T_t^{\dagger G} + T_t, \quad X_H = H^{-1}(T_t^* H + H T_t).$$

The coordinating Zeta calculation sharpens the transfer through the explicit isometry $\mathcal{S} = (I + B)^{1/2} : (E, H) \rightarrow (E, G)$. Set $Z = [\mathcal{S}, T_t] \mathcal{S}^{-1}$. Its complete Hermitian error and the convergent Sylvester integral give

$$|\|X_H\|_H - \|X_G\|_G| \leq \|Z + Z^{\dagger G}\|_G \leq \alpha^{-1} \|[B, A] + t[B, R]\|_G, \quad [B, R]v = (B e_0) \ell(v) - e_0 \ell(Bv).$$

Both original metrics, the original unit and the ordered residue terms remain. Commuting discrepancies give exactly equal control radii. For the actual Fourier-projected representative $\mathcal{R}$ and its theta boundary $\mathcal{B}$, the full identities are

$$W_H(0) = -(\mathcal{R}^* \mathcal{B} + \mathcal{B}^* \mathcal{R}), \\ (D_L^2 - k D_L) \mathcal{R} - \mathcal{R} (A^2 - k A) = (D_L - k) \mathcal{B} + \mathcal{B} A.$$

The resulting original-metric control radius gives both inequalities of the full Laplacian numerical-range parabola (FC18), including the zero-radius case. These statements preserve the actual arithmetic commutator and boundary that a numerical endpoint estimate must evaluate.

Result R62: quotient curvature and the complete fourth derivative. Retain the exact original coefficient sequence $0 \rightarrow F \xrightarrow{I} E \rightarrow E/F \rightarrow 0$ and a constant quotient lift J_F . Its least-period-norm lift and quotient Gram $K(t)$ are the full Schur formulas (FC21). With $C = [I, J_F]$ they satisfy

$$\det(I^* \Pi^* \Pi I) \det K = |\det C|^2 |\det \Pi|^2, \quad \partial_t \partial_t \log \det K = -\frac{|t|^2}{|u|^2} \mathfrak{c}_F(\Pi^* \Pi).$$

The positive constituent curvature is therefore compensated in this same coefficient quotient, with both curvatures vanishing at zero and with opposite nonzero leading coefficients. The full proof includes quotient-lift independence, basis covariance and the literal comparison with the original theta quotient metric.

The residue continuation evaluates the pure jets as well. If $\psi = \log \det(I^* \Pi(t)^* \Pi(t) I)$ and $\phi(t) = \log \det(I^* \Pi(0)^* \Pi(t) I)$ near zero, then

$$\left. \frac{d^4}{dx^4} \psi(x) \right|_0 = 2 \operatorname{Re} \phi^{(4)}(0) + 6c_F(\Pi(0)^* \Pi(0))/|u|^2.$$

The full ordered recursion for $\Pi^{(n)} = \Pi Q_n$, its explicit Q_4 including $3R^2/u^2$, and the complete trace-log formula in (RCX30)–(RCX32) evaluate the remaining pure term. The forced period equation retains $u\Pi R$, and its original source primitive retains tKR . The exact Pascal translation preserves the t -derivatives of order at least two at fixed u , while its scalar factor retains the first-derivative trace shift $2p \operatorname{Re} a$. Its pure u -derivatives are the explicitly retained terms in (RCX.u5)–(RCX.u6) below.

The same constant quotient lift and the complete two-parameter period matrix give the exact compensating Hessian

$$\partial_{\bar{a}} \partial_b \log \det K = -\operatorname{Tr}(H^{-1} Z_a^* Z_b), \quad a, b \in \{u, t\}, \quad H = I^* \Pi^* \Pi I, \quad Z_a = N \Pi \Omega_a I.$$

Indeed the displayed Schur determinant identity holds at each (u, t) , its constant frame factor has zero derivative, and $\log |\det \Pi|^2$ is pluriharmonic where Π is invertible. Applying (SC.u2) proves the equality for both diagonal and both mixed entries, with the original quotient metric and frame preserved. The earlier quadratic vanishing statement is its t entry at $t = 0$; the u entry retains the B_χ/u normal term of (SC.u3).

The complete ordered derivative recursion now is (RCX.u1)–(RCX.u2):

$$Q_{0,0} = I, \quad Q_{r+1,s} = \partial_u Q_{r,s} + \Omega_u Q_{r,s}, \quad Q_{r,s+1} = \partial_t Q_{r,s} + \Omega_t Q_{r,s}, \quad \partial_u^r \partial_t^s \Pi = \Pi Q_{r,s}.$$

Flatness proves compatibility of all derivative orders. In particular,

$$\begin{aligned} Q_{2,0} &= C_\chi^2/u^4 + (2C_\chi - C_\chi B_\chi - B_\chi C_\chi)/u^3 + (B_\chi^2 - B_\chi)/u^2, \\ Q_{1,1} &= C_\chi A_t/u^3 + (A_t - B_\chi A_t)/u^2. \end{aligned}$$

All earlier pure t jets, including $3R^2/u^2$ in the fourth derivative, are the same $r = 0$ slice. Along a specified curve $(u(s), t(s))$, the exact metric variation inserted into the original residue Rayleigh-quotient formula is

$$\dot{H}_{\text{full}} = \Omega_{\text{path}}^* H_{\text{full}} + H_{\text{full}} \Omega_{\text{path}}, \quad \Omega_{\text{path}} = \dot{u} \Omega_u + \dot{t} \Omega_t, \quad H_{\text{full}} = \Pi^* \Pi.$$

The full forced-equation descendant also remains, by (RCX.u4):

$$2u\Pi_{tt} + u^2\Pi_{utt} + k\Pi_t + ku\Pi_{ut} + \Pi R + u\Pi_u R = \Pi \Omega_u L_t.$$

It composes with the unchanged theta-source map j_E and retains its original boundary primitive.

Finally, with $p = \dim F$ and $h_a(t) = -\Phi(-a) - ta$, the original translated phase gives

$$\begin{aligned} \psi_a - \psi &= 2p \operatorname{Re}(h_a(t)/u), \\ \partial_u(\psi_a - \psi) &= -ph_a(t)/u^2, \\ \partial_u^2(\psi_a - \psi) &= 2ph_a(t)/u^3, \\ \partial_u \partial_t(\psi_a - \psi) &= pa/u^2. \end{aligned}$$

These are the exact derivatives proved in (RCX.u5)–(RCX.u6), through the full translated connection (DT.14)–(DT.16). Their Hermitian mixed derivatives vanish because the retained scalar difference is pluriharmonic, while these pure derivatives remain in the ordered recursion.

Result R63: all holonomies reconstruct the original source. The complete proof (H1)–(H66), including (H49a)–(H49g), and the typed continuation (HDI1)–(HDI24) retain the original half-density source $\Psi_N = \mathcal{U}_k \mathcal{V}|_{\mathcal{P}_N}$, the full relative Hilbert fibre, and $g = 2\xi$. For $L > 0$ the exact map and inverse are

$$\mathcal{Z}_{L,\theta}\psi(r) = \sum_{a \in \mathbb{Z}} e^{ia\theta} \psi(r + aL), \quad \psi(r + aL) = \int_0^{2\pi} e^{-ia\theta} \mathcal{Z}_{L,\theta}\psi(r) \frac{d\theta}{2\pi},$$

$$\int_0^{2\pi} M_{N,\theta} \frac{d\theta}{2\pi} = M_N, \quad M_{N,\theta} = (\mathcal{Z}_{L,\theta}\Psi_N)^*(\mathcal{Z}_{L,\theta}\Psi_N).$$

Fourier series in the original translation index prove the isometry. The quasi-periodic basis has coefficients $L^{-1/2} \hat{\psi}((2\pi n + \theta)/L)$; the full zero mode remains. The length- mL source has the exact finite character decomposition $M_N(mL, 0) = m^{-1} \sum_j M_N(L, 2\pi j/m)$, with the isometry factors $\sqrt{m}$ and $1/\sqrt{m}$ retained. Its coefficient cover is $\mathbb{C}[z, z^{-1}] \rightarrow \mathbb{C}[w, w^{-1}]$, $z \mapsto w^m$, with the full basis $1, w, \dots, w^{m-1}$ and the multiplication carry z .

For the same original remainder map J_N , let $C_N, C_{N,\theta}$ be the actual least-norm sections, and retain the literal relation columns B_{rel} . The complete relation identity is

$$C_N - C_{N,\theta} = B_{\text{rel}} X_{N,\theta}, \quad X_{N,\theta} = (B_{\text{rel}}^* M_{N,\theta} B_{\text{rel}})^{-1} B_{\text{rel}}^* M_{N,\theta} C_N,$$

$$G_N = \overline{G}_N + \mathcal{D}_N, \quad \mathcal{D}_N = \int (C_N - C_{N,\theta})^* M_{N,\theta} (C_N - C_{N,\theta}) \frac{d\theta}{2\pi}.$$

Every relation has its original theta primitive. Empty relation columns give $\mathcal{D}_N = 0$. With the actual weighted source constant $\kappa_{a,N}$ and $\delta_L = \kappa_{a,N}/(e^{aL} - 1) < 1$, the full inverse-chord and block-matrix proof gives

$$(1 - \delta_L^2) G_N \preceq \overline{G}_N \preceq G_N.$$

For the four-volume comparison, compute the common bound $\delta_L = \kappa_{a,N}/(e^{aL} - 1) < 1$ on the retained maximal source $N_* = 2q + 2$ and restrict it to each of the four endpoint spaces, as in (H42)–(H43). Its error is then at most $2q \log(1/(1 - \delta_L^2))$. This bound is attached to the arithmetic average of the canonical quotient forms. The exact comparison is $G_N = \overline{G}_N + \mathcal{D}_N$, with the displayed positive integral of original relation corrections; the continuous equal-image complex and its cochain contraction realizing $\overline{G}_N$ are given in R64 and the full HCD proof. The individual phase-source comparisons have their stronger current common-polynomial-source controls in (HC13)–(HC14). Their averaging retains this separate positive correction and all of its original entries. The supplied two-point sharpness is strengthened by the explicit compactly supported full-circle source in (HDI22)–(HDI24), with original calibration mass seven and phase factors $e^{\pm i\theta}$.

Result R64: continuous cochain descent and the exact completion map. The full proof (HCD1)–(HCD29), including the actual source bounds (HCD2a)–(HCD2c), considers relation fields $\mathcal{B}$ and the common-image fields $\mathcal{P}^{\text{eq}}$ over $d\theta/(2\pi)$. At the fixed cutoff N , choose $0 < \eta < 1$ and retain the actual weighted source constant $\kappa_{\beta,N}$. The explicit circumference $L \geq \beta^{-1} \log(1 + \kappa_{\beta,N}/\eta)$ gives the uniform equivalence in (HCD2a)–(HCD2c) used in the following bounded maps. Repetition and Bochner mean give the bounded coefficient isomorphism

$$[\mathcal{B} \hookrightarrow \mathcal{P}^{\text{eq}}] \simeq [\chi \mathcal{P}_{N-q} \hookrightarrow \mathcal{P}_N] \oplus [\mathcal{B}^0 \xrightarrow{I} \mathcal{B}^0], \quad hP = P - \Delta \text{av} P.$$

The full calculation proves $dh + hd = I - \Delta \text{av}$, and the quotient is the original $E = \mathbb{C}[S]/(\chi)$ with metric $\overline{G}_N$. Its relation gap retains the weighted cross term. If $\overline{C}_N = \int C_{N,\theta} d\theta/(2\pi)$, $a_C = C_N - \overline{C}_N$ and $h_\theta = C_{N,\theta} - \overline{C}_N$, then

$$\int a_C^* M_{N,\theta} h_\theta \frac{d\theta}{2\pi} = a_C^* M_N a_C, \quad \mathcal{D}_N = \int h_\theta^* M_{N,\theta} h_\theta \frac{d\theta}{2\pi} - a_C^* M_N a_C.$$

For every $L > 0$, the full shifted-density proofs (CQ1)–(CQ29) and (HDI11)–(HDI21) identify the subsequent completed phase quotient with the weighted values at positive-mass sampled roots. Its exact map from E has kernel $(p_\theta)/(\chi)$, where p_θ is the squarefree sampled product and χ retains every primary multiplicity. The original one-fold packet satisfies $(\chi_{h,1}) = (h)$; its selected-root mass is $|g^{(r)}(\rho)/h^{(r)}(\rho)|^2/L > 0$, with the original leading coefficient retained. The complete primary-coordinate inverse gives the nilpotent kernel at every sampled root and the full block at every unsampled root.

The diagonal root projections give an explicit measurable field. Only finitely many phases can sample a fixed root of χ , so its completed direct integral is zero. The evaluation maps form the actual cochain map from the continuous common-image complex to this completed complex; its map on degree-one cohomology has kernel all of E . On an original split label λ , its inverse image of the receiving represented zero is the full represented coefficient kernel, while the inverse image of τ is the singleton $\{\tau\}$. This specifies the operation and its kernel with the original support and all finite classes present.

Result R65: quadratic generator transfer with an exact residue norm. The complete proof (HG1)–(HG25), including (HG11a), uses the actual relation-cost endomorphism $D = G_N^{-1}\mathcal{D}_N$, the original $T_t = A + tR - kI/2$, and $R = e_0\ell$. It proves

$$|\epsilon_{\overline{G}_N}(t) - \epsilon_{G_N}(t)| \leq \frac{\| [D, A] + t[D, R] \|_{G_N}}{1 - \delta_L^2} \leq \frac{\delta_L^2}{1 - \delta_L^2} \|T_t\|_{G_N}.$$

The exact square-root isometry and Sylvester integral preserve the full Hermitian error. The sharper scalar constant follows from the complete spectral-projection decomposition of the original self-adjoint discrepancy: its commutator norm is at most its spectral diameter times the original generator norm.

For any actual self-adjoint discrepancy $B = G^{-1}(H - G)$, let $x = e_0, y = G^{-1}\ell^*$ and retain

$$\begin{aligned} a_0 &= \|Bx\|_G^2, \quad c_0 = \|x\|_G^2, \quad d_0 = \|y\|_G^2, \quad f_0 = \|By\|_G^2, \quad p_0 = \langle x, Bx \rangle_G, \quad r_0 = \langle y, By \rangle_G, \\ T_{\text{res}} &= a_0d_0 + c_0f_0 - 2p_0r_0, \quad \Delta_{\text{res}} = (a_0c_0 - p_0^2)(d_0f_0 - r_0^2), \\ \| [B, R] \|_G^2 &= \frac{T_{\text{res}} + \sqrt{T_{\text{res}}^2 - 4\Delta_{\text{res}}}}{2}. \end{aligned}$$

The full coordinating residue proof is reproduced in (HG12)–(HG15), including both negative cross terms, singular Gram matrices, rank zero, rank one, repeated singular values and $q = 1$. The primary quantity remains $\| [B, A] + t[B, R] \|_G$ with its complete cancellation.

Equations (HG16)–(HG20) give explicit L, s, m, J from the actual weighted and derivative source Grams. The holomorphic Schur inverse is certified on the specified smaller strip, with its neighborhood, and the finite mean obeys

$$\alpha G_N \preceq H_{m,J} \preceq \beta G_N, \quad \alpha = (1 - \xi_J)(1 - \delta_L^2 - \varepsilon) > 0, \quad \beta = 1 + \varepsilon.$$

The exact discrepancy is $B_{m,J} = -D + E_{m,J}$, where the finite-tail spectrum lies in $[-\rho, \varepsilon]$, $\rho = \xi_J + (1 - \xi_J)\varepsilon$. The proof retains its entire commutator and gives the corresponding spectral-diameter bounds. The finite representative retains both ordered theta boundary terms in (HG23). The resulting original-metric radius enters the complete Laplacian numerical-range parabola (HG25); the same proved metric comparison gives the residue-coefficient bounds (HG24).

Result R66: the original degree cost and full continuous closure. The complete proof (HD1)–(HD10) fixes h, k, L and a real sample u_0 , with $S_0 = k/2 + iu_0$ and $a_N = (1, S_0, \dots, S_0^N)$. For the unchanged original polynomial Gram it constructs the polynomial P_N with its displayed coefficient vector c_N :

$$\Lambda_N = a_N M_N^{-1} a_N^* \uparrow \infty, \quad c_N = M_N^{-1} a_N^* / \Lambda_N, \quad P_N(S_0) = 1, \quad \|\mathcal{V}P_N\|^2 = 1/\Lambda_N.$$

The divergence is proved by the original exponential moments, Hilbert representation, holomorphic Fourier uniqueness and the Gaussian measure argument. At an actually positive sampled mass $\omega_0 = (2\pi/L)m_{h,k}(u_0)$ this gives the exact degree cost

$$\kappa_{a,N} \geq (e^{aL} - 1)(\omega_0 \Lambda_N - 1) \longrightarrow \infty.$$

The same columns have full holonomy mean squared norm tending to zero, while their selected phase squared norm remains at least ω_0 . Evaluation factors through the original E exactly when $\chi(S_0) = 0$, with the fully calculated primary kernel.

The coordinating complete proof (CR1)–(CR14), including (CR12a)–(CR12c), extends this to the entire original source. Multiplication by the literal χ is the onto isometry

$$L^2(|\chi|^2 m du) \xrightarrow{\times \chi} L^2(m du), \quad f \longmapsto \chi f,$$

with its division inverse defined almost everywhere. Polynomial density therefore proves that the continuous relation closure is the whole Hilbert source. If Π_N is its actual finite relation projection and $s : E \rightarrow \mathcal{P}_{q-1}$ its fixed remainder section, then

$$R_N = (I - \Pi_N)s, \quad J_N R_N = I_E, \quad G_N = R_N^* R_N \downarrow 0, \quad \overline{\text{graph } J} = L^2(m du) \times E.$$

All limits here fix the original h, k and retain the complete finite coefficient frame. At singular phase Grams the exact receiving space is $T_\theta(\mathcal{P}_N)/T_\theta(\mathcal{B}_N)$, with kernel $J_N(\ker T_\theta)$ on E . Its measurable minimum form gives $0 \preceq \overline{G}_N \preceq G_N$ by testing the original R_N . The independent full completion proof further gives the relation gap as the integral of the squared projection of $T_\theta R_N$ onto $T_\theta \mathcal{B}_N$. Every finite $\overline{G}_N$ is positive for each original $k \geq 1$: outside a countable set of one-fold phases all sampled weights are positive. At an actual positive sampled root, its fixed-phase quotient/source ratio diverges by (CR14). These exact maps and limits impose no unstated rate in the distinct tensor parameter k and do not identify the relative gap with its absolute limit.

Result R67: the original pushforward over the absolute tau base. The complete original Tau Base construction works over the pointed blueprint $\mathbf{F}_{1,\tau} = \{\tau, 1\}$ and its four-point chart $+, - < \eta < \sigma$. In its declared coefficient-diagram category the projective resolution of the constant object is

$$0 \longrightarrow P_\eta \xrightarrow{v \mapsto (v, -v)} P_+ \oplus P_- \xrightarrow{(u,v) \mapsto u+v} \mathbb{C} \longrightarrow 0.$$

At the two lower points the last map is the identity; at the two upper points its kernel is the displayed anti-diagonal. This proves exactness pointwise. Applying Hom gives the actual derived pushforward

$$\mathbf{A}_\tau(F) = [F_+ \oplus F_- \xrightarrow{r_+ - r_-} F_\eta].$$

For the retained theta diagram $\mathcal{T} = (V, V, \mathcal{B}, 0)$ the restrictions are Θ and $\Theta\mathcal{F}$, so its first cohomology is $Q = \mathcal{B}/\Theta V$. Tensoring the pointwise resolution, with the original signs $(-1)^{\sum_{j < i} |x_j|}$, gives top cohomology $Q^{\otimes k}$. Its numerator is $\mathcal{B}^{\otimes k}$ and its boundary subspace is the sum of tensors having a factor ΘV ; tensoring the quotient maps proves that identification. The right adjoint is the full injective complex $K_\tau(W) = [I_\eta W \rightarrow I_+ W \oplus I_- W]$, in degrees $-1, 0$, with the two signed restrictions. The complete Tau Base proof and (DB1)–(DB13) give the adjunction, tensor signs and residue-dual arrows, including the original full Taylor units.

For a full actual packet h of $g = 2\xi$, keep $E_h = \mathbb{C}[s]/(h)$, $v_h = j_h(g/h) \in E_h^\times$, and its original section $\sigma_h : E_h \hookrightarrow Q$. For the cyclic tensor-sum quotient $E = \mathbb{C}[S]/(\chi_{h,k})$, the two separately typed injections are

$$\eta_{h,k}[P] = v_h^{\otimes k} P(A_h^{(k)})1 \quad \text{in } E_h^{\otimes k}, \quad \sigma_h^{\otimes k} \eta_{h,k} : E \hookrightarrow Q^{\otimes k}.$$

Their injectivity follows from the defining cyclic annihilator, the invertible full tensor unit and the tensor of the original left inverse of σ_h . These are the original arithmetic classes in the pushforward

over τ . Restriction to σ is a separate cochain map from that pushforward, defined by its original restrictions; its homotopy and fibre are retained in the full original and transcript-continuation proofs.

The full-source pushforward also has the proved maps from every declared mixed support $\lambda = (W, S; \alpha)$. Its coefficient copies retain the independent outer label and the coefficient mask, including an empty mask at a present label. For one original leg the exact map is

$$\eta_W : V/W \longrightarrow \mathcal{B}_\Omega/\Theta W, \quad [v] \longmapsto [\Theta v]_W.$$

Injectivity follows from injectivity of Θ . Its image is the kernel of the map to $\mathcal{B}_\Omega/\Theta V$: a representative maps to zero precisely when it is Θv . These maps applied to each admitted coefficient copy give the full kernel $(V/W)^\alpha$, without altering the outer label. The full coefficient masks, action intertwiners and zero-coordinate insertion maps are proved in (MCF42)–(MCF51) and (D9)–(D14).

For tensor sources retain the declared subcomplex $\mathbf{C}_\lambda^\bullet \subseteq \mathbf{C}_{\text{full}}^\bullet$. The exact comparison on top quotient classes has kernel

$$\frac{d\mathbf{C}_{\text{full}}^{k-1} \cap \mathbf{C}_\lambda^k}{d\mathbf{C}_\lambda^{k-1}}.$$

The isomorphism sends a represented boundary to its original class; its inverse chooses the same representative. Both are well-defined because their equivalence relation is the displayed denominator. The ordered polynomial divisions and signed original tensor primitive in (ISM38)–(ISM43) compute the actual member $[d\tilde{K}_v]_\lambda$ of this kernel for each canonical metric secant whose compared top representatives lie in $\mathbf{C}_\lambda^k$. It vanishes at this label exactly when $d\tilde{K}_v \in d\mathbf{C}_\lambda^{k-1}$.

The original finite source tower also retains its actual type: D sends W_m^{src} to W_{m+1}^{src} , giving the quotient arrow and residual of (R1b)–(R1c). The source-level preimages of the arithmetic length-two quotient in (MCF47)–(MCF51), together with the shifted filtrations proved in MW and MRE, carry those adjacent-level arrows. Their low-degree one-leg tail is acyclic at the full source $W = V$; the proper-source tail retains $H^1 = V/W$, and the two-leg complex retains its degree-zero diagonal kernel. Thus the original τ pushforward and its arithmetic quotient are connected through the actual source kernel and filtered preimages throughout this edition.

Result R68: the arithmetic cyclic image inside the full period family. For $d = \deg h$, the original one-factor exponential family over $\mathbb{C}[u, t]$ is $[\mathbb{C}[u, t][s] \xrightarrow{u\partial_s + h(s) - t} \mathbb{C}[u, t][s] ds]$. Use the original primitive $\Phi'_h = h$, its fixed additive constant, and the oriented rapid-decay contours in the admitted sector of $u \neq 0$. Their full matrix $\Pi_h(u, t)$ has columns $\int_{\Gamma_j} s^a e^{(\Phi_h(s) - ts)/u} ds$, $0 \leq a < d$. The complete period proof retains its determinant, ray phases, contour orientations and all coefficients. With independent parameters $t_1, \dots, t_k$, the unchanged rectangular matrix

$$\mathcal{P}(u, \mathbf{t}) = \left(\bigotimes_{i=1}^k \Pi_h(u, t_i) \right) \eta_{h,k}$$

is injective, because each period factor is invertible and $\eta_{h,k}$ is injective. The exact derivative at the undeformed parameter is

$$-u \sum_{i=1}^k \partial_{t_i} \mathcal{P}(u, \mathbf{0}) = \mathcal{P}(u, \mathbf{0}) A_{h,k}.$$

Differentiating each exponential inserts s_i ; the cyclic intertwining and commutation of the full tensor unit with $\sum A_i$ prove the formula. It uses the original sum coordinate, with no division by k . The full (DP23)–(DP33) proof supplies the coefficient-ring reductions, exact left inverse on this image, original metric pullback and separately defined finite-field external product. All nonsemisimple jets and root collisions have their stated domains there.

The complete singular-parameter connection acts on this same rectangular image. Write $f_i(s_i) = \Phi_h(s_i) - t_i s_i$ and retain the literal monic divisions

$$f_i(s_i)s_i^b = (h(s_i) - t_i)q_{i,b} + r_{i,b}, \quad (C_h(t_i))_b = r_{i,b}, \quad (B_h)_b = q'_{i,b}.$$

The differential remainder is $r_{i,b} - uq'_{i,b}$, with $C_h(t_i) = f_i(A_h(t_i))$. The original one-factor matrix is $\Omega_{u,h}(u, t_i) = -C_h(t_i)/u^2 + B_h/u$, and $\partial_u \Pi_h = \Pi_h \Omega_{u,h}$. The complete division and contour proof is in the boundary connection chapter and (XD.u1)–(XD.u6), applied to the displayed original h -variable. On the ordered product complex the degree- j cochain operator is exactly

$$\nabla_u^{(j)} = \partial_u - \frac{\sum_i f_i}{u^2} + \frac{k-j}{u}.$$

Its cochain identity follows one slot at a time from the degree-zero/degree-one identity: increasing exterior degree removes exactly one $1/u$ term. Every exterior sign and the original ordered form are retained.

Set $\Pi_{\text{prod}} = \bigotimes_i \Pi_h(u, t_i)$; let $\Omega_{u,\text{prod}}$ be the sum of the k matrices $\Omega_{u,h}(u, t_i)$ acting in their respective tensor slots. The product rule gives the exact original map

$$\partial_u \mathcal{P} = \Pi_{\text{prod}} \Omega_{u,\text{prod}} \eta_{h,k}.$$

For the full original positive tensor coefficient Gram G at the specified finite source cutoff, retain the explicit left inverse

$$\ell_\eta = (\eta_{h,k}^* G \eta_{h,k})^{-1} \eta_{h,k}^* G, \quad \ell_\eta \eta_{h,k} = I.$$

The inverse exists because $\eta_{h,k}$ is injective and G is positive on the original full tensor source. The complete parameter defect is therefore

$$\partial_u \mathcal{P} - \mathcal{P}(\ell_\eta \Omega_{u,\text{prod}} \eta_{h,k}) = \Pi_{\text{prod}}(I - \eta_{h,k} \ell_\eta) \Omega_{u,\text{prod}} \eta_{h,k}.$$

Substitution and factoring prove this equality, retaining the actual transverse component and full unit in $\eta_{h,k}$. The observed form remains $\eta_{h,k}^* \Pi_{\text{prod}}^* \Pi_{\text{prod}} \eta_{h,k}$, with its original source comparison Gram. The cyclic $\chi_{h,k}$ -potential has its own connection (XD.u1)–(XD.u7); this injection, left inverse and transverse map give the precise comparison with the product potential.

On the complete primary slice $h = (s - \rho)^m, t_i = 0$, the exact product period matrix, source-unit character projectors, terminal arithmetic eigenclass and finite-field boundary are proved in (BTP.1)–(BTP.11) and (BTF.1)–(BTF.11). The complex invariant dimension is $(m^k + m(-1)^k)/(m+1)$; the actual finite-field inertia dimension is that number when $kc = 0$ and zero otherwise, with $c = -(-\rho)^{m+1}/(m+1)$. The original unit-weighted coefficient map and all its factorial losses are (PC30a)–(PC30g) and (BPC.1)–(BPC.14), on precisely their stated coefficient-map domains. These full proofs retain the one-factor vanishing as its $k = 1$ case and carry each surviving tensor character to its actual boundary stalk.

Result R69: actual theta dilation and the moving-parameter flow. On the original theta source use $U_a F(x) = F(x/a)$ for positive real a ; its Mellin action is a^s . The two-leg action is $(\phi, \psi) \mapsto (U_a \phi, a U_{1/a} \psi)$. The complete scaling proof computes the original source boundary of its packet section and the finite cocycle, so the quotient section intertwines this action with the full exponential of the original jet operator, including all nilpotents. For the h exponential family the regular connection operator is

$$L = u \partial_t - s, \quad [u \partial_s + h - t, L] = 0, \quad \frac{dC_b}{db} = -C_b A_h(t + ub), \quad C_0 = I.$$

The two nonzero commutators are $-u$ and $+u$. The finite matrix ODE defines the entire transport; on the admitted period domain it is exactly $\Pi_h(u, t)^{-1} \Pi_h(u, t + ub)$. Its special-fibre matrix is $C_b(0, t) =$

$e^{-bA_h(t)}$. At $b = \log p$ this gives the original p^{-A_h} , corresponding to $U_{1/p}$, for every positive real p . The separate global algebraic curve power map $z \mapsto z^p$ has the additional domain $p \in \mathbb{Z}_{>0}$; there its pullback is $dz/z \mapsto p dz/z$ and the divisor depth is multiplied by that integer. The corrected full source states these distinct parameter domains explicitly.

For the retained reflection-stable cyclic polynomial, put $\varepsilon = (-1)^q$, $q = \deg \chi$, and $RP(S) = P(k - S)$. The full reflection proof gives

$$RA_\chi(t)R = kI - A_\chi(\varepsilon t), \quad RC_b^\chi(u, t)R = e^{-kb}C_{-b}^\chi(-\varepsilon u, \varepsilon t).$$

Here the cyclic potential is $\Phi'_\chi = \chi$, with the original endpoint $\Phi_\chi(0) = 0$. Its reflection gauge is $\exp((\Phi_\chi(k) - kt)/u)R$ on $u \neq 0$; the unsquared contour sign remains. The matrix identity extends through $u = 0$ by the entire ODE, rather than by evaluating that singular gauge. The same proof retains the inverse-transpose dual and the original moment-line factor e^{-kb} .

The same finite transport has its complete original u -derivative. Keep $\Omega_{u,h} = -C_h(t)/u^2 + B_h/u$, $\Omega_{t,h} = -A_h(t)/u$, and $t_b = t + ub$. Differentiating the exact matrix formula at fixed b gives

$$\begin{aligned} \partial_u C_b &= -\Omega_{u,h}(u, t)C_b + C_b(\Omega_{u,h}(u, t_b) + b\Omega_{t,h}(u, t_b)), \\ \partial_t C_b &= -\Omega_{t,h}(u, t)C_b + C_b\Omega_{t,h}(u, t_b). \end{aligned}$$

Indeed $\partial_a \Pi^{-1} = -\Omega_{a,h}\Pi^{-1}$; the target derivative is $\Pi(u, t_b)(\Omega_{u,h} + b\Omega_{t,h})(u, t_b)$. This proves the pull-back connection under the actual base map $(u, t) \mapsto (u, t + ub)$, including $b\partial_t$. It is the polynomial restriction of the fully proved (APU23) transport. These equations hold on the original nonzero- u contour domain; the same entire finite-matrix ODE supplies the regular transport through $u = 0$. The reflection and inverse-transpose dual retain the stated parameter pullbacks and original moment-line factor; their derivatives follow by these same inverse and chain rules on the unchanged maps.

Result R70: the original Taylor unit is an exact formal gauge. Let ν be the degree-less-than- d polynomial representing the full v_h , so $\gcd(h, \nu) = 1$. The exact rings are $\widehat{B} = \mathbb{C}[s][[u, t]]$ and $\widehat{B}_\nu = \mathbb{C}[s, \nu^{-1}][[u, t]]$. The coefficientwise pole quotient is $M[[u, t]]$, $M = \mathbb{C}[s, \nu^{-1}]/\mathbb{C}[s]$. Multiplication by h on M has an exact inverse H : Bezout coefficients for h, ν^n prove surjectivity on each principal part and coprimality proves injectivity. With $E_0 = u\partial_s - t$ the inverse on the pole complex is

$$J = \sum_{n \geq 0} (-HE_0)^n H.$$

The displayed order is essential. Each factor HE_0 raises parameter order, making every coefficient a finite sum. The proper-rational section of the quotient gives the explicit contraction and retraction in (UG8)–(UG11). Multiplication by the full ν then gives

$$\nu(u\partial_s + h - t)\nu^{-1} = u\partial_s + h - t - u\nu'/\nu.$$

It commutes with the same $L = u\partial_t - s$. Its endpoint on E_h is exactly multiplication by ν_h ; the signed completed external product recovers exactly $\eta_{h,k}$ after the original cyclic inclusion. The complete (UG1)–(UG19) proof includes every tensor homotopy and the inverse-unit residue dual on its original reflection-stable domain.

The formal gauge carries the complete regular form of the singular-parameter operator. Put $f = \Phi_h - ts$. On the original two formal complex terms define

$$H_j = u^2\partial_u - f + (1 - j)u, \quad j = 0, 1, \quad H_1 D = D H_0, \quad D = u\partial_s + h - t.$$

The commutator of $u^2\partial_u$ with D is $u^2\partial_s$, and that of $-f$ with D is $u(h - t)$. Their sum is uD , canceled by the extra u on the degree-zero term. This proves the cochain identity. These operators act coefficientwise on the stated completed rings. After the specified localization in u , they are $u^2\nabla_u^{(j)}$, with the same degree terms as (APU1)–(APU4). Since ν is independent of u, t ,

$$\nu H_j \nu^{-1} = H_j, \quad H_1(\nu D \nu^{-1}) = (\nu D \nu^{-1}) H_0.$$

These are operators on the transported gauge terms; multiplication by f commutes with ν . The polynomial-to-localized inclusion commutes with H_j . Its cohomology isomorphism, proved by the full contraction J , consequently has inverse commuting with the induced H : multiply the intertwining identity by that inverse on both sides. This proves compatibility without assigning strict horizontality to an uncomputed chain retraction. The exact homotopy and full gauge endpoint remain (UG8)–(UG19).

The existing $L = u\partial_t - s$ satisfies $[H_j, L] = uL$, because its two nonzero terms are $u^2\partial_t$ and $-us$. Including the derivative of $1/u$ therefore gives $[H_j/u^2, L/u] = 0$ on the localized complex. At the original formal fibre H_1 is multiplication by $-\Phi_h$, commuting with the entire $[\nu] = v_h$. On the ordered k -fold complex the same calculation gives $u^2\partial_u - \sum_i(\Phi_h - t_i s_i) + (k-j)u$; the original signed tensor gauge and its source endpoint retain their full degree terms and Taylor units.

Result R71: analytic pole residues, their connection and their endpoint. Return to the original h -potential $\Phi'_h = h$ with its specified additive constant. For fixed $u \neq 0$, write $w = e^{(\Phi_h(s)-ts)/u}$ and let $\mathcal{P}_\nu$ be the finite set of distinct zeros of ν , of size r . The exact pole sequence now is

$$0 \longrightarrow M \xrightarrow{u\partial_s + h - t} M \xrightarrow{F \mapsto (\text{Res}_p(wF ds))_p} \mathbb{C}^{\mathcal{P}_\nu} \longrightarrow 0.$$

The highest pole term $c(s-p)^{-n}$ maps to $-unc(s-p)^{-n-1}$, proving injectivity. A zero-residue Laurent series wF has a meromorphic primitive without a logarithm; taking the principal part of that primitive divided by uw proves exactness in the middle. The lift $1/(w(p)(s-p))$ proves surjectivity. The original polynomial cohomology therefore injects into the analytic localization, with precisely this residue cokernel. A full basis consists of the original d polynomial classes and the simple-pole classes $1/(s-p)$.

Let $P = \text{diag}(p)$ and let B_0 have each column the original constant-polynomial vector e_0 . Their exact connection and transport are

$$L = u\partial_t - \begin{pmatrix} A_h(t) & B_0 \\ 0 & P \end{pmatrix}, \quad C_{\text{ext},b} = \begin{pmatrix} C_b & K_b \\ 0 & e^{-bP} \end{pmatrix}, \quad K_b = - \int_0^b C_c B_0 e^{-(b-c)P} dc.$$

The off-diagonal term follows from $L(1/(s-p)) = -p/(s-p) - 1$ and the displayed ODE. The full routed period determinant is $\det \Pi_{\text{ext}} = \det \Pi_h(2\pi i)^r \prod_p w(p)$, with positive small-loop orientations. Under the actual unit gauge the weight is w/ν ; all periods agree because $(w/\nu)(\nu F) = wF$.

At the original formal endpoint let Q_0 have columns $-(h(s) - h(p))/((s-p)h(p))$ in E_h . Then

$$A_h Q_0 = B_0 + Q_0 P, \quad J_0 = [I \ Q_0], \quad \ker J_0 = \{(-Q_0 c, c) : c \in \mathbb{C}^r\}, \quad J_0 C_{\text{ext},b}(0,0) = e^{-bA_h} J_0.$$

Multiplication by the full v_h after J_0 is the gauge endpoint. These are explicit comparison maps between the analytic extension and the original formal fibre. The complete (AP1)–(AP26) proof retains all higher poles, the ordinary dual, the zero-pole case and the exceptional $p = 0$ phase; it proves no evaluation of the formal inverse at a nonzero complex u .

The full connection of this analytic extension now includes its u direction, as proved in (APU1)–(APU23). Write $f(s, t) = \Phi_h(s) - ts$, and let Q have columns

$$Q_p(s, t) = \frac{f(s, t) - f(p, t)}{s - p} - \frac{h(s) - t}{d + 1}, \quad p \in \mathcal{P}_\nu.$$

The first polynomial has degree d and leading coefficient $1/(d+1)$. Its division by $h-t$ has that constant quotient; the derivative correction is zero and the displayed remainder has degree less than d . In the original polynomial and simple-pole columns the exact matrix is

$$\Omega_{u,\text{ext}} = \begin{pmatrix} -C_h(t)/u^2 + B_h/u & -Q/u^2 \\ 0 & -\text{diag}(f(p, t))/u^2 \end{pmatrix}, \quad \partial_u \Pi_{\text{ext}} = \Pi_{\text{ext}} \Omega_{u,\text{ext}}.$$

Apply $\nabla_u = \partial_u - f/u^2$ to $1/(s-p)$ and separate $f(p)/(s-p)$ from its complete polynomial divided difference to prove this formula. The original t -matrix remains $-u^{-1} \begin{pmatrix} A_h(t) & B_0 \\ 0 & P \end{pmatrix}$. The full block flatness, including its off-diagonal block, is proved in (APU8)–(APU12) using these literal remainders.

Put $W_{\text{res}} = \text{diag}(e^{f(p,t)/u})$. The weighted-residue row matrix is $\mathcal{R} = [0, W_{\text{res}}]$; the positively oriented loop row matrix is $(2\pi i)\mathcal{R}$. Differentiation gives

$$\partial_u W_{\text{res}} = -\text{diag}(f(p, t))W_{\text{res}}/u^2, \quad \partial_t W_{\text{res}} = -PW_{\text{res}}/u.$$

Thus $\partial_a \mathcal{R} = \mathcal{R}\Omega_{a,\text{ext}}$ for $a = u, t$; both residue and loop maps are horizontal, with their original $2\pi i$ factors retained. The entire transport has the two derivative identities in R69 with the full extension matrices. Equation (APU23) proves the resulting shifted endpoint and residue diagrams, including $b\Omega_{t,\text{ext}}(u, t + ub)$.

Multiplication by the complete ν commutes with the parameter operators and transports the entire frame; its weight is still w/ν . Its inverse-transpose dual and unchanged endpoint J_0 are proved in (APU18)–(APU22). The original theta-source observation is exactly $\sigma_h[\nu]J_0$, retaining the entire unit. When ν is constant, $r = 0$ and every pole block, row and additional loop is empty; the same equations reduce to the full original polynomial connection and its unit gauge. These maps retain the analytic family, the specified formal endpoint and the formal coefficient operations of R70.

Result R72: the signed arithmetic determinant variation. On the unchanged common source $\mathcal{P}_{2q}$ interpolate the original Gamma and arithmetic densities as $m_t = (1-t)m_\Gamma + tm_{\text{ar}}$, and write M_N, H_N, R_N, G_N for the original source Gram, relation Gram, minimum section and quotient Gram. The complete (AT1)–(AT22) proof preserves the determinant-line sign and gives

$$\begin{aligned} V_N &= \det G_N = \det M_N / \det H_N, & \dot{R}_N &= -B_N H_N^{-1} B_N^* \Delta M_N R_N, \\ \dot{G}_N &= R_N^* \Delta M_N R_N, & \ddot{G}_N &= -2R_N^* \Delta M_N B_N H_N^{-1} B_N^* \Delta M_N R_N. \end{aligned}$$

Both negative squared norms in the logarithmic second derivative remain. The full (AV1)–(AV32) calculation proves that equality holds exactly when $\Delta M_N R_N = 0$. With P_N, Q_N the original same-metric polynomial and relation projections, retain

$$\begin{aligned} U &= Q_{2q-1} + Q_{2q} - Q_q, & W &= P_{2q-1} - P_{q-1} + P_{2q} - P_q, \\ C(t) &= M_{2q}(t)^{-1} \Delta M_{2q}, & \mathcal{B}(t) &= \log \frac{V_{q-1}(t)V_q(t)}{V_{2q-1}(t)V_{2q}(t)}. \end{aligned}$$

Subtracting the four exact determinant derivatives proves

$$\mathcal{B}(1) - \mathcal{B}(0) = \int_0^1 \text{Tr}((U - W)C) dt.$$

The full proof also gives its absolutely convergent pointwise kernel integral against $m_{\text{ar}} - m_\Gamma$, including zeros of the arithmetic density. It assumes no bounded pointwise ratio of the two densities.

The newly supplied canonical-projector formula has the exact operator correspondence

$$\Pi_N = R_N G_N^{-1} R_N^* M_{2q} = P_N - Q_N, \quad \mathcal{A} = \Pi_{q-1} + \Pi_q - \Pi_{2q-1} - \Pi_{2q} = U - W.$$

Here every R_N is padded by the original coefficient inclusion into the same $\mathcal{P}_{2q}$. The decomposition $\mathcal{P}_N = R_N E \perp_M \chi \mathcal{P}_{N-q}$ proves the first equality: subtracting $R_N \pi_\chi p$ from p gives an original relation, and canonical orthogonality annihilates its cross Gram. The restricted remainder map is the inverse of $R_N : E \rightarrow \text{ran } \Pi_N$. Thus the signed trace in this result is precisely the supplied trace, with $\text{Tr } \mathcal{A} = 0$.

For two source forms M_0, M_1 , let $\Delta = R_1 - R_0 = B_N(Z_0 - Z_1)$, where $Z_i = (B_N^* M_i B_N)^{-1} B_N^* M_i C_{\text{rem}}$. The complete original remainder lift is C_{rem} . Orthogonality expands both secants with their actual signs:

$$\begin{aligned} G_1 - aG_0 &= R_1^*(M_1 - aM_0)R_1 + a\Delta^* M_0 \Delta, \\ bG_0 - G_1 &= R_0^*(bM_0 - M_1)R_0 + \Delta^* M_1 \Delta. \end{aligned}$$

At the first endpoint the relation space is zero and $\Delta = 0$. Equations (ISM4)–(ISM12) prove these identities and their full source enclosure; the revised coefficient $2q - 1$ and all smaller common-source controls are retained at that same proof site.

For admitted degrees $i \leq j$, the canonical reverse restriction $T_{ij} = G_i^{-1} G_j$ has the exact cross trace $\text{Tr}(\Pi_i \Pi_j) = \text{Tr} T_{ij}$. Indeed $R_j^* M R_i = G_j$, by the original relation-valued section difference, and substitution in the trace proves the identity. The full proof (ISM21)–(ISM26) retains the cross term between the two projector differences in $\text{Tr}(\mathcal{A}^2)$. Centering C by its actual trace mean gives

$$|\mathcal{B}'| \leq \sqrt{\left(\text{Tr}(C^2) - \frac{(\text{Tr} C)^2}{2q+1} \right) \text{Tr}(\mathcal{A}^2)}.$$

Weighted self-adjointness and Hilbert–Schmidt Cauchy–Schwarz prove this on the original metric. Furthermore (ISM28)–(ISM37) constructs a finite matrix polynomial $C^{[L]}$, with exact residual, whose signed integral j_L encloses the correction:

$$j_L - e_L \leq \mathcal{B}(1) - \mathcal{B}(0) \leq j_L + e_L, \quad e_L \leq \vartheta^{L+1} \sqrt{K_D(8q-6)} \rightarrow 0.$$

All of $C^{[L]}$, j_L , e_L , ϑ , K_D are explicitly defined and proved in (RMT19)–(RMT21), with their identity to the ISM notation. This supplies a constructed residual on the actual finite source, preserving the signed center and all arithmetic entries.

Result R73: full spectral data and the exact source isometry. The nested original flags give both U and W the full spectrum $0^{[q]}, 1^{[2]}, 2^{[q-1]}$. The explicit original-metric isometry T in (AW9)–(AW10) intertwines them and gives

$$U = TWT^{-1}, \quad \text{Tr}((U - W)C) = \text{Tr}(WT^{-1}[C, T]).$$

Its original arithmetic observation is explicitly $\sigma_h^{\otimes k} \eta J_{2q} T$, with defect $\sigma_h^{\otimes k} \eta J_{2q} (T - I)$ and kernel $\mathcal{P}_{q-1}^\perp$. Thus its action on original classes is retained rather than presumed to be identity. For all eigenvalues $b_1 \leq \dots \leq b_{2q+1}$ of the actual relative source Gram, counted with multiplicity, the complete spectral proof gives

$$|\mathcal{B}(1) - \mathcal{B}(0)| \leq \log \frac{b_{q+2}}{b_q} + 2 \sum_{j=1}^{q-1} \log \frac{b_{2q+2-j}}{b_j} \leq (2q-1) \log \frac{b_{2q+1}}{b_1}.$$

The full (FS1)–(FS35) proof gives strict pointwise inequality for nonscalar C on the literal polynomial flags, and an exact limiting positive-coefficient-metric family. Its moment obstruction is explicitly nonzero; the constructed limiting family is not assigned an arithmetic density. The complete (AW1)–(AW23), (WS1)–(WS39) and independent spectral proofs retain the precise equality scope and all relative eigenvalues.

The complete full-spectrum, trace-norm, overlap, centered Hilbert–Schmidt and angle controls now apply jointly to this same integrand. With their full definitions (RMT8)–(RMT13), the current stronger bound at this site is

$$|\mathcal{B}(1) - \mathcal{B}(0)| \leq J_q = \int_0^1 \min\{E_q, T_q, O_q, S_q, A_q\} dx \leq \mathcal{L}_q(D) \leq (2q-1) \log \kappa.$$

Here $T_q = d_x \|U_x - W_x\|_1/2$ retains the exact trace norm, O_q its two proved overlap majorants, and S_q the supplied centered variance bound. Their complete proofs and the exact source correspondence are in (RMT3)–(RMT15). Every entry bounds the identical signed trace, so taking its pointwise minimum and integrating proves the displayed inequality. The angle entry A_q uses the actual common moment path and its proved positivity in R74; for a general positive coefficient form the other four entries and the finite signed certificate retain their proved scope.

Result R74: all-degree nonlinear control from the original moments. The inherited endpoint-window proof already gives the canonical principal-angle comparison, nonlinear arcosh transport, strict moment positivity and signed tensor theta primitive (EW.25)–(EW.28), (EW.35a)–(EW.35c), (EW.46a)–(EW.48). The complete (AGT1)–(AGT19) and (AA1)–(AA44) proofs independently re-derive these structures and sharpen the selected window $n = r = q$: crossing its same four projection terms changes the guaranteed moving-angle count from $2q$ to $2q - 1$. The full comparison (EP1)–(EP36) proves every coefficient, metric and operator identification and retains the inherited proof’s broader window domain. For two nested cutoffs the actual relation-valued difference of minimum sections satisfies

$$D_{ij} = R_i - R_j, \quad G_i - G_j = D_{ij}^* M D_{ij}, \quad K_{ij} = G_i^{-1/2} G_j G_i^{-1/2}.$$

The eigenvalues of K_{ij} are the squared principal cosines of the original minimum-section subspaces, with their full multiplicities. The pairs $(q - 1, 2q)$ and $(q, 2q - 1)$ give the original $\mathcal{B}$ as their combined negative log determinant. The second pair has at least one exact zero angle in an ambient space of dimension $2q - 1$. Retaining the full angle lists thus leaves $m = 2q - 1$ possibly nonzero contributions.

For $\chi(S) = \sum_{j=0}^q a_j S^j$ define $\chi^{\#_k}(S) = \sum_{j=0}^q \bar{a}_j (k - S)^j$. The actual line $\bar{S} = k - S$ gives $\chi^{\#_k}(S) = \overline{\chi(S)}$ there, with $\chi^{\#_k} \in \mathcal{P}_q$. If $\mathcal{B}$ vanished, its first pair would coincide, forcing $1 \perp \chi \mathcal{P}_q$ and hence $0 = \int |\chi(k/2 + iu)|^2 m_t(u) du > 0$. Thus $\mathcal{B}(t) > 0$ throughout the actual interpolation. The exact projection-difference spectra and concavity of $\sqrt{1 - e^{-x}}$ now yield

$$|\dot{\mathcal{B}}| \leq m \sqrt{1 - e^{-\mathcal{B}/m}} (c_{\max} - c_{\min}), \quad \left| 2 \operatorname{arcosh}(e^{\mathcal{B}(1)/(2m)}) - 2 \operatorname{arcosh}(e^{\mathcal{B}(0)/(2m)}) \right| \leq I_q \leq \log \kappa,$$

where $\kappa = b_{2q+1}/b_1$ is the original finite relative Gram ratio. The proof includes the explicit hyperbolic-cosine endpoint interval, the $q = 1$ case, every zero angle, the original theta primitive of D_{ij} and its full source energy. It applies in particular to the original full quartet value $q = [1 + k(m_h - 1)](k + 1)^2$, where m_h denotes the quartet’s common zero order; this last m_h is distinct from the angle count $2q - 1$.

In the preceding formula the refined radius is the actual I_q of (RMT13), with $a = m = 2q - 1$; it divides each of the five same-source pointwise controls by the exact derivative denominator of the nonlinear coordinate. Differentiating $\mathcal{H}_m(B) = 2 \operatorname{arcosh}(e^{B/(2m)})$ gives $1/(m \sqrt{1 - e^{-B/m}})$, so that integration proves this replacement of the former radius $\log \kappa$. Its inverse is $2m \log \cosh(z/2)$, with continuous value zero at zero. Write $B_0 = \mathcal{B}(0)$, $H_0 = \mathcal{H}_m(B_0)$. For every constructed finite order L , the resulting current interval is

$$\begin{aligned} \mathcal{B}(1) &\geq \max \left\{ 0, B_0 - J_q, 2m \log \cosh \left(\frac{\max\{0, H_0 - I_q\}}{2} \right), B_0 + j_L - e_L \right\}, \\ \mathcal{B}(1) &\leq \min \left\{ B_0 + J_q, 2m \log \cosh \left(\frac{H_0 + I_q}{2} \right), B_0 + j_L + e_L \right\}. \end{aligned}$$

Each entry is a bound proved in R72–R73 or obtained by applying the increasing inverse just calculated; their intersection therefore contains the same actual endpoint. The complete proof (RMT19)–(RMT22) retains the computed geometric residual and original theta comparison; it also proves the scalar and $q = 1$ cases without dropping any coefficient or source mass. The same new upper endpoint is substituted into the central arithmetic and inverse-return estimates at R44–R45 and R47 and their complete earlier proofs.

For the original arbitrary window $n \geq q, r \geq 1$, the same crossed pairing $(n-1, n+r)$ and $(n, n+r-1)$ gives the proved count $a(q, r) = \min(q, r+1) + \min(q, r-1)$ in (EP17)–(EP25). It improves the inherited count $2 \min(q, r)$ by one exactly when $r = q$. Its entire loss, norm factor, full Taylor units and supported theta primitive retain the original definitions.

The complete proofs following these results retain the original arithmetic Grams as actual data. Their uniform control in tensor degree is the continuing analytic calculation; no missing estimate has been introduced as an assumption in the bounds just proved.

The complete preceding proofs now carry the corrected source kernels, full two-parameter connections, actual tensor specializations and current signed metric controls through their earlier dependent calculations. The original arithmetic norm and endpoint lower products remain in the same estimates. The finite signed residual is explicitly constructed for each fixed source; its constants remain the original arithmetic spectral data as the tensor order varies. The complete source provenance and earlier editions accompany this revised reader.

S1.1 Exact finite operator quotients of the tau-base theta cohomology

Owner-directed continuation, 12 September 2026. Mathematical derivation and research draft; no new analytic theorem below is claimed to have been checked by Lean.

S1.1.1 0. Inputs, provenance, and the new result

This note continues TAU_BASE_MODEL.md, rather than moving the programme back to a finite-field variety. Its arithmetic coefficient object is the original split semiring

$$G(R) = \{\tau\} \sqcup \{r^\bullet : r \in R\}, \quad e = 0_R^\bullet.$$

The geometric base remains the one-point absolute pointed base described there. The quotient

$$p_{\mathbb{Z}} : G(\mathbb{Z}) \longrightarrow \mathbb{Z}$$

and its square with $G(\mathbb{C}) \rightarrow \mathbb{C}$ remain part of the marked object. No ideal norm, Euler factor, scaling parameter, Gaussian, or completion factor is changed here.

The supplied derived formalization (PR #6, 5f6ee6575550d8a20c6fc3990359cb4f67855f80) provides the actual reconstruction, internal quotient, homology-kernel equivalence, and compatible kernel actions. Its finite-jet module supplies the balanced tensor-quotient comparison with the split-reflection square. Those results are reused; this note does not duplicate their Lean implementation.

The new analytic step computes the previously only surjective finite Mellin-jet observation as an exact operator quotient. For every polynomial h whose roots lie in the open critical strip, it constructs

$$Q/h(D)Q \xrightarrow{\sim} E_h/g_h E_h, \quad Q[h(D)] \xrightarrow{\sim} \ker(g_h : E_h \rightarrow E_h),$$

with $E_h = \mathbb{C}[t]/(h)$ and $g = 2\xi$. It then constructs finite spectral projectors on the original Q , not only quotients of Q , and identifies the torsion subsheaf of the balanced analytic realization with $\mathcal{O}/(2\xi)$. Their kernels, original supported zeros, nilpotent actions, and trace-producing residue pairing are all retained.

The general existence of spectral realizations of zeta zeros is prior literature (not a novelty claim here): see R. Meyer, *A spectral interpretation for the zeros of the Riemann zeta function*, arXiv:math/0412277. The contribution of this note is the explicit comparison in the specified workbench, together with its original SplitZero quotients and its complete finite kernel calculation.

S1.1.2 1. The exact arithmetic complex and its operator

Retain

$$V = \{\phi \in \mathcal{S}(\mathbb{R}) : \phi(-x) = \phi(x), \phi(0) = 0, \int_{\mathbb{R}} \phi(x) dx = 0\},$$

$$\mathcal{B} = \{F \in C^\infty(\mathbb{R}_{>0}) : \sup_{x>0} x^b |(-x\partial_x)^k F(x)| < \infty \text{ for all } b \in \mathbb{Z}, k \geq 0\}.$$

The source maps, with their original factors, are

$$D = -x\partial_x, \quad \Theta\phi(x) = \sum_{n \in \mathbb{Z} \setminus \{0\}} \phi(nx), \quad \mathcal{M}F(s) = \int_0^\infty F(x) x^s \frac{dx}{x}.$$

The Fourier transform is $\widehat{\phi}(\xi) = \int_{\mathbb{R}} \phi(x) e^{-2\pi i x \xi} dx$. Poisson and the two moment conditions put ΘV in $\mathcal{B}$. Also $D\Theta = \Theta D$, and D preserves V .

Set

$$A = \mathbb{C}[t], \quad t \cdot F = DF, \quad t \cdot \phi = D\phi,$$

$$C_+ = [V \xrightarrow{\Theta} \mathcal{B}] \text{ in degrees } 0, 1, \quad Q = \mathcal{B}/\Theta V.$$

The existing injectivity proof of Θ gives $H^0(C_+) = 0$ and $H^1(C_+) = Q$.

This is the one-leg subcomplex of the actual tau-base chart complex

$$C_{+-} = [V \oplus V \xrightarrow{\Theta\phi - \Theta\widehat{\psi}} \mathcal{B}].$$

Its inclusion is $\phi \mapsto (\phi, 0)$ in degree zero and the identity in degree one. The quotient complex is the second copy of V in degree zero. The explicit section is $\psi \mapsto (\psi, \psi)$. The operator on that second copy is $1 - D$, because $D\widehat{\psi} = (1 - D)\psi$. Thus the additional joint-support degree-zero cohomology is retained in this split exact sequence; it is not included in Q and then silently discarded.

The actual source multiplier is

$$g(s) = 2\xi(s) = s(s-1)\pi^{-s/2}\Gamma(s/2)\zeta(s),$$

$$H_\phi(s) = c(s)M_+\phi(s), \quad c(s) = \frac{2\pi^{s/2}}{s(s-1)\Gamma(s/2)}, \quad M_+\phi(s) = \int_0^\infty \phi(x) x^s \frac{dx}{x}.$$

On the open strip $\mathcal{S} = \{0 < \Re s < 1\}$, $c(s)$ is holomorphic and nowhere zero. The source identity is

$$\mathcal{M}\Theta\phi = gH_\phi.$$

The specific function

$$\phi_*(x) = (4\pi^2 x^4 - 6\pi x^2) e^{-\pi x^2}$$

has $H_{\phi_*} = 1$. Consequently

$$H_{P(D)\phi_*}(s) = P(s), \quad \mathcal{M}\Theta(P(D)\phi_*) = g(s)P(s).$$

These are identities with the stated Gaussian and $g = 2\xi$; no rescaling is performed.

S1.1.3 2. A continuous inverse to the actual Euler differential

For any $\rho \in \mathbb{C}$, define on the subspace $\{H \in \mathcal{B} : \mathcal{M}H(\rho) = 0\}$

$$S_\rho H(x) = x^{-\rho} \int_x^\infty H(t) t^{\rho-1} dt.$$

All powers use the real logarithm on $x, t > 0$. Direct differentiation gives

$$(D - \rho)S_\rho H = H.$$

Endpoint control. Write $x = e^y$, $h(y) = H(e^y)$, and $\sigma = \Re \rho$. At $y \geq 0$, the displayed tail and a bound $|h(t)| \leq C_N e^{-Nt}$ give

$$|S_\rho H(e^y)| \leq \frac{C_N}{N - \sigma} e^{-Ny} \quad (N > \sigma).$$

At $y \leq 0$, the zero moment changes the same expression into the negative lower tail. A bound $|h(t)| \leq C'_N e^{Nt}$ gives

$$|S_\rho H(e^y)| \leq \frac{C'_N}{N + \sigma} e^{Ny} \quad (N + \sigma > 0).$$

Differentiating uses $(S_\rho H)'_y = -\rho S_\rho H - H(e^y)$, so every derivative has the same family of estimates. This proves membership in $\mathcal{B}$ and continuity in its stated seminorms. The homogeneous solution $x^{-\rho}$ fails the required rapid decrease unless its coefficient is zero. Thus $D - \rho$ is injective, and

$$(D - \rho)\mathcal{B} = \ker(F \mapsto \mathcal{M}F(\rho)).$$

Mellin intertwining gives

$$\mathcal{M}(S_\rho H)(s) = \frac{\mathcal{M}H(s)}{s - \rho},$$

with the removable value filled at $s = \rho$.

There is also a source inverse. For $\rho \in \mathcal{S}$ and $\phi \in V$ with $H_\phi(\rho) = 0$, use the same tail for $x > 0$ and extend evenly. The nonvanishing of $c(\rho)$ gives $M_+\phi(\rho) = 0$. Near zero the formula is

$$S_\rho \phi(x) = - \int_0^1 u^{\rho-1} \phi(xu) du.$$

Differentiation under this integral proves smoothness at zero in every order. The function is even and its value at zero is zero. The upper-tail formula proves Schwartz decay at infinity. Finally

$$(1 - \rho) \int_{\mathbb{R}} S_\rho \phi(x) dx = \int_{\mathbb{R}} \phi(x) dx = 0,$$

so the second moment condition is preserved. This proves the source range identity

$$(D - \rho)V = \ker(\phi \mapsto H_\phi(\rho)) \quad (\rho \in \mathcal{S}).$$

At the level of Taylor coefficients $\phi(x) = \sum_{j \geq 1} a_{2j} x^{2j}$, the local expression is $-\sum_{j \geq 1} a_{2j} x^{2j} / (\rho + 2j)$, interpreted to each finite Taylor order with its smooth remainder. All denominators and the minus sign are retained. Endpoints 0, 1 are not included in this source range theorem.

S1.1.4 3. Every finite operator test, without choosing zeros first

Choose any finite set of distinct centres $\rho_1, \dots, \rho_r \in \mathcal{S}$ and positive integers m_i . Define the particular polynomial

$$h(t) = \prod_{i=1}^r (t - \rho_i)^{m_i}, \quad d = \deg h, \quad E_h = A/(h).$$

This defines the test; it does not presume that any centre is a zeta zero. The Chinese-remainder map is

$$\theta_h : E_h \xrightarrow{\sim} \prod_i \mathbb{C}[z_i]/(z_i^{m_i}), \quad [P(t)] \mapsto [P(\rho_i + z_i)].$$

For a holomorphic germ family f at the centres, $j_h f$ denotes its Taylor jets transported back by θ_h^{-1} . In particular $g_h = j_h g$ retains the original local units of g .

Iterate Section 2 through the factors of h . Uniqueness makes the inverse independent of their chosen order. This gives the continuous inverse

$$S_h : \ker(j_h \mathcal{M}) \longrightarrow \mathcal{B}, \quad h(D)S_h = \text{id}.$$

The exact range identities are

$$h(D)\mathcal{B} = \ker(j_h \mathcal{M}), \quad h(D)V = \ker(j_h H).$$

Surjectivity on the source follows from $H_{P(D)\phi_*} = P$. Surjectivity of the target jet map follows directly from finite Mellin interpolation: on an interval in $y = \log x$, the functions $e^{\rho_i y} y^j / j!$ are linearly independent. For a nonnegative smooth bump η positive on a subinterval, the Gram matrix

$$G_{(i,j),(k,l)} = \int \eta(y) e^{(\rho_i + \bar{\rho}_k)y} \frac{y^{j+l}}{j!l!} dy$$

is positive definite. Multiplying its inverse into the prescribed jet vector produces a compactly supported smooth preimage. This is only an interpolation device; it does not define or alter the arithmetic Weil pairing.

Consequently the vertical arrows in

$$\begin{array}{ccc} V/h(D)V & \xrightarrow{\bar{\theta}} & \mathcal{B}/h(D)\mathcal{B} \\ \alpha_h \downarrow \wr & & \wr \downarrow \beta_h \\ E_h & \xrightarrow{\times g_h} & E_h \end{array}$$

are actual A -module isomorphisms:

$$\alpha_h[\phi] = j_h H_\phi, \quad \beta_h[F] = j_h \mathcal{M}F.$$

An inverse to α_h sends the unique polynomial representative P of degree less than d to $[P(D)\phi_*]$. An inverse to β_h is any of the above explicit interpolation lifts, taken modulo $h(D)\mathcal{B}$; the class is independent of that choice by the range theorem.

S1.1.5 4. The kernel and quotient of the global arithmetic operator

Both V and $\mathcal{B}$ are torsion-free A -modules: every factor $D - \rho$ is injective, since its homogeneous solution cannot be Schwartz at infinity. Over the PID A , they are flat. The bounded complex C_+ is therefore a valid flat model for derived tensoring. The displayed isomorphism computes

$$C_+ \otimes_A^{\mathbf{L}} E_h \simeq [E_h \xrightarrow{\times g_h} E_h]$$

in degrees zero and one. It is the base-change of the actual theta complex, not a newly declared spectral complex with an assigned differential.

The original exact sequence $0 \rightarrow V \xrightarrow{\Theta} \mathcal{B} \rightarrow Q \rightarrow 0$ also gives

$$0 \rightarrow Q[h(D)] \xrightarrow{\kappa_h} E_h \xrightarrow{\times g_h} E_h \rightarrow Q/h(D)Q \rightarrow 0.$$

Here $Q[h(D)] = \ker(h(D) : Q \rightarrow Q)$. The maps are explicit:

- Given $[F] \in Q[h(D)]$, uniquely write $h(D)F = \Theta\phi$. Then $\kappa_h[F] = j_h H_\phi$.
- The quotient observation sends $[F]$ to $j_h \mathcal{M}F$ modulo $g_h E_h$.
- For $P \in \ker(g_h : E_h \rightarrow E_h)$, choose its polynomial representative of degree less than d and set

$$\partial_h(P) = [S_h \Theta(P(D)\phi_*)] \in Q[h(D)].$$

The last expression is defined because its theta input has zero jets modulo h . Replacing P by $P + hR$ changes the result by $\Theta(R(D)\phi_*)$. Thus it is independent of representatives and is the inverse of κ_h onto its kernel. The two injectivity and surjectivity assertions also follow directly by lifting representatives in the preceding exact sequence; no dimension-only argument is needed.

All maps commute with D , with $U_a F(x) = F(x/a)$, and with compactly supported multiplicative convolution. On E_h , the scaling action is multiplication by $j_h(a^s)$, including its entire finite nilpotent Taylor polynomial.

At one centre, retain $g(\rho + z) = u(z)z^r$, where $u(0) \neq 0$ (and $r = 0$ is allowed). For test order m , the two cohomology modules have dimension $\min(m, r)$. When $r = 0$, multiplication by g_h is invertible. The derived amplitude complex is then acyclic, while its reconstructed supported homology still has each labelled internal zero.

The degree-zero term is $Q[h(D)]$; the degree-one term is $Q/h(D)Q$. Their finite alternating traces cancel. The arithmetic packet trace below is the degree-one action, or equivalently its explicitly constructed direct summand in the original Q . The canonical truncation triangle retains the degree-zero term rather than relabelling it as zero.

S1.1.6 5. Exact finite spectral projectors on the original cohomology

Now let Z be any finite set of actual nontrivial zeros and retain their full multiplicities r_ρ . Put

$$h_Z(t) = \prod_{\rho \in Z} (t - \rho)^{r_\rho}, \quad E_Z = A/(h_Z), \quad v_Z(s) = g(s)/h_Z(s).$$

The quotient v_Z is entire and its germs are nonzero at every point of Z . Hence $v_{Z,h} = j_{h_Z} v_Z$ is an invertible element of E_Z . This inverse retains the actual Taylor coefficients of g/h_Z ; it is not set to one.

Here $g_{h_Z} = 0$, and the exact sequence becomes

$$Q[h_Z(D)] \xrightarrow[\kappa_Z]{\sim} E_Z, \quad Q/h_Z(D)Q \xrightarrow[\beta_Z]{\sim} E_Z.$$

There is a further map that must be calculated, not assumed: the inclusion of the kernel into Q , followed by the quotient. For $P \in E_Z$,

$$\mathcal{M}(S_{h_Z}\Theta(P(D)\phi_*)) = \frac{gP}{h_Z} = v_Z P.$$

Therefore this kernel-to-quotient comparison is precisely

$$\boxed{\beta_Z q_Z \partial_Z = M_{v_{Z,h}} : E_Z \xrightarrow{\sim} E_Z.}$$

Define

$$\sigma_Z = \partial_Z \circ M_{v_{Z,h}}^{-1} : E_Z \longrightarrow Q,$$

$$\boxed{\Pi_Z = \sigma_Z J_Z : Q \longrightarrow Q, \quad J_Z[F] = j_{h_Z} \mathcal{M}F.}$$

Then

$$\boxed{J_Z \sigma_Z = \text{id}, \quad \Pi_Z^2 = \Pi_Z, \quad \text{im } \Pi_Z = Q[h_Z(D)], \quad \ker \Pi_Z = h_Z(D)Q.}$$

This gives the actual equivariant direct sum

$$\boxed{Q = Q[h_Z(D)] \oplus h_Z(D)Q.}$$

A representative formula is completely determined. For $F \in \mathcal{B}$, let $P_{Z,F}$ be the unique polynomial of degree less than $\deg h_Z$ representing $v_{Z,h}^{-1} j_{h_Z} \mathcal{M}F$. Then

$$\boxed{\Pi_Z[F] = [S_{h_Z}\Theta(P_{Z,F}(D)\phi_*)].}$$

For a simple actual zero ρ , this specializes to

$$\Pi_{\{\rho\}}[F] = \frac{\mathcal{M}F(\rho)}{g'(\rho)} \left[x^{-\rho} \int_x^\infty \Theta\phi_*(t) t^{\rho-1} dt \right].$$

The displayed denominator is the actual $g'(\rho) = 2\xi'(\rho)$; it is not omitted. The bracketed class is an actual nonzero eigenclass in Q , proved by the exact sequence, even though its representative is only an eigenvector modulo the theta relation.

For finite packets the projectors satisfy

$$\Pi_Z \Pi_W = \Pi_{Z \cap W}, \quad \Pi_{Z \cup W} = \Pi_Z + \Pi_W \quad (Z \cap W = \emptyset).$$

These follow from the direct sums, coprimality of disjoint packet polynomials, and commutation with D . Inclusions of finite packets therefore give compatible invariant subspaces and quotient observations. No convergence of an infinite sum of projectors is asserted.

S1.1.7 6. Carry every projector through the original split quotient

For any vector space M the single-active-fibre lift is $M^\tau = \{\tau\} \sqcup \{m^\bullet : m \in M\}$. For a submodule N use exactly

$$q_N^{\text{sp}} : M^\tau \rightarrow (M/N)^\tau, \quad m^\bullet \mapsto [m]^\bullet, \quad \tau \mapsto \tau.$$

This is the original coequalizer of the relation inclusion and its internal-zero companion. Its universal property is the one implemented in PR #6, including arbitrary noncancellative target semi-modules.

Consequently the finite observation has the split-linear equivalence

$$(Q/h(D)Q)^\tau \xrightarrow{\sim} G(E_h/g_h E_h), \quad [F]^\bullet \mapsto (j_h \mathcal{M} F \bmod g_h E_h)^\bullet.$$

The domain is being used as a split semimodule, not as an unconstructed ring. A class in $h(D)Q$ maps to the supported zero, and external absence alone maps to external absence.

Lift the projector as

$$\tilde{\Pi}_Z(\lambda, [F]) = (\lambda, \Pi_Z[F]).$$

This formula applies to the actual nonempty support faces of the tau-base theta model; their degree-one transports are the stated identities of Q . At bottom it is the original zero map of the bottom module. The full reconstruction interface permits a nonzero bottom fibre when a subsequent diagram requires one; it is not silently specialized away on an opposite-index dual diagram.

For disjoint packets,

$$\tilde{\Pi}_Z \tilde{\Pi}_W = \varepsilon, \quad \varepsilon(\lambda, x) = (\lambda, 0).$$

This is the supported lift of the zero linear operator, not the constant external-zero map. More uniformly, take $\Pi_\emptyset = 0_Q$ and lift it to ε . The scalar representation

$$G(\text{End}_{\mathbb{C}} Q) \longrightarrow \text{End}_{G(\mathbb{C})}(Q^\tau)$$

sends $f^\bullet$ to its split lift and sends τ to the constant- τ map. It is a unital semiring morphism and sends the supported scalar zero to ε .

Retain smaller admitted source labels For a subspace $W \subset V$, first use its specified enlargement $W_D = \mathbb{C}[D]W$ and keep the map

$$\mathcal{B}/\Theta W \longrightarrow Q_{W_D} := \mathcal{B}/\Theta W_D, \quad \ker = \Theta W_D/\Theta W.$$

For a D -stable W , define the ideal

$$J_{W,h} = \{j_h H_\phi : \phi \in W\} \subseteq E_h.$$

It is an ideal because $H_{P(D)\phi} = PH_\phi$ and every element of E_h has a polynomial representative. The same target range calculation gives

$$Q_W/h(D)Q_W \cong E_h/(g_h J_{W,h}).$$

Enlarging to $W + \mathbb{C}[D]\phi_*$ makes $J_{W,h} = E_h$. The exact finite comparison kernel is

$$g_h E_h / (g_h J_{W,h}).$$

Thus the finite equality for the full arithmetic relation space has a precise smaller-label comparison. It is not asserted for every original W without this kernel.

S1.1.8 7. The Hausdorff observation and the remaining global kernel

The projectors just constructed have continuous finite-rank representatives on $\mathcal{B}$: J_Z is continuous, E_Z is finite dimensional, and S_{h_Z} is continuous on its zero-jet domain. They annihilate ΘV , hence also its closure. They therefore descend to

$$Q^H = \mathcal{B} / \overline{\Theta V}.$$

The finite observation still has kernel exactly $h_Z(D)Q^H$. Indeed

$$\ker J_Z = h_Z(D)\mathcal{B} + \Theta V,$$

and continuity gives $\overline{\Theta V} \subset \ker J_Z$. Hence adding the closure to the right side leaves it unchanged. The same finite section yields a continuous direct sum

$$Q^H = \sigma_Z(E_Z) \oplus h_Z(D)Q^H.$$

The algebraic packet $Q[h_Z(D)]$ injects into this Hausdorff quotient: its composite with J_Z is already an isomorphism onto E_Z . No conclusion about vanishing of the entire algebraic-to-Hausdorff kernel follows from this finite statement.

Let

$$\mathcal{R}_\infty = \bigcap_{Z \text{ finite}} \ker \Pi_Z = \bigcap_{Z \text{ finite}} h_Z(D)Q.$$

The map $Q \rightarrow \prod_\rho \mathcal{O}_\rho / (g)$ has exactly this kernel. Every nonzero polynomial whose roots are in $\mathcal{S}$ acts bijectively on $\mathcal{R}_\infty$. To verify this, its kernel on Q lies in the finite packet at its zero centres; its cokernel is supported there as calculated in Section 4. On the complementary summand it is bijective, and its inverse preserves all other commuting finite projectors. This proves injectivity and surjectivity on the intersection.

The continuation retains $\mathcal{R}_\infty$ and its scaling action. Finite packets do not prove it zero. A topological spectral-synthesis theorem or a global cohomological trace argument must address that specific invariant module rather than infer its disappearance from finite-jet isomorphisms.

7.1 The global balanced kernel has a computed local-cohomology complement Work now on the analytic strip $\mathcal{S}$, with its sheaf $\mathcal{O}$ and sheaf $\mathcal{K}$ of meromorphic functions. Form the sheafified balanced realization

$$\mathcal{M}_Q = \mathcal{O} \otimes_A Q, \quad \beta : \mathcal{M}_Q \longrightarrow \mathcal{O}/(g), \quad b \otimes [F] \longmapsto [bMF].$$

Let $\text{tors}_{\mathcal{O}}(\mathcal{M}_Q)$ denote its torsion subsheaf: a germ is in it when some nonzero holomorphic germ annihilates it. This is torsion over the specified analytic coefficient ring; its connection to the original split support is the reconstruction of the inclusion and quotient maps below.

Theorem. The actual Mellin map restricts to an isomorphism

$$\beta|_{\text{tors}} : \text{tors}_{\mathcal{O}}(\mathcal{M}_Q) \xrightarrow{\sim} \mathcal{O}/(g).$$

Moreover, $\mathcal{N} = \ker \beta$ has a canonical $\mathcal{K}$ -module structure, and the displayed map canonically splits the sequence:

$$\boxed{\mathcal{M}_Q \cong \mathcal{O}/(g) \oplus \mathcal{N}, \quad \mathcal{K} \otimes_{\mathcal{O}} \mathcal{N} \cong \mathcal{N}.}$$

Proof at every stalk. Fix $\rho \in \mathcal{S}$ and set $x = s - \rho$. If $g(\rho) \neq 0$, Section 4 with $h = t - \rho$ proves that $D - \rho$ is bijective on Q . Consequently x is invertible on $\mathcal{M}_{Q,\rho}$, and this module is a module over the meromorphic field $\mathcal{O}_\rho[1/x]$. Its torsion is zero, as is $\mathcal{O}_\rho/(g)$.

If $r = \text{ord}_\rho g > 0$, the finite projector for this one full packet gives

$$Q = Q[(D - \rho)^r] \oplus (D - \rho)^r Q.$$

On the second summand, $(D - \rho)^r$ is bijective: it is injective by the direct-sum intersection, and

$$(D - \rho)^r Q = (D - \rho)^{2r} Q$$

follows by applying $(D - \rho)^r$ to the direct sum. Hence $D - \rho$ itself is bijective there. Tensoring the direct sum with $\mathcal{O}_\rho$ gives a first summand $\mathcal{O}_\rho/(x^r)$, on which β is the isomorphism calculated in Section 5, and a second summand on which x is invertible. The map β kills the second summand because it is in $x^r \mathcal{M}_{Q,\rho}$, while x^r annihilates its target. Every nonzero germ of $\mathcal{O}_\rho$ is a unit times a power of x , so that second summand is a module over $\mathcal{K}_\rho$ and is torsion-free.

This proves the stated torsion isomorphism at every stalk. It glues without choosing neighbourhood projectors: both the torsion subsheaf and the restricted map β are intrinsic. The inverse of that isomorphism, followed by the torsion inclusion, is the global section of β . Local inverses to nonzero holomorphic scalars on $\mathcal{N}$ are unique, so they glue to its $\mathcal{K}$ -module structure. This proves the theorem.

7.2 The extraction is an actual local-cohomology map At the same stalk the principal-ideal local-cohomology complex is the explicit localization complex

$$R\Gamma_{(x)}(\mathcal{M}_{Q,\rho}) = [\mathcal{M}_{Q,\rho} \longrightarrow \mathcal{M}_{Q,\rho}[1/x]], \quad \text{degrees } 0, 1.$$

The decomposition just proved computes it:

$$\boxed{R\Gamma_{(x)}(\mathcal{M}_{Q,\rho}) \xrightarrow{\sim} (\mathcal{O}_\rho/(g))[0].}$$

The finite torsion summand maps to zero upon localization; the meromorphic summand maps isomorphically to itself. The map to the displayed target is β in degree zero and zero in degree one. Thus the supported arithmetic divisor is the actual cohomological image of the localization kernel, not a prescribed deletion of a list of spectral points.

Before analytic extension there is the corresponding operator-localization map

$$Q \longrightarrow A[h_Z^{-1}] \otimes_A Q,$$

with kernel $Q[h_Z(D)]$ and cokernel zero, because $h_Z(D)$ is invertible on its complementary summand. Its supported lift sends that kernel to the internal supported zero, not to external absence.

At every original label λ , reconstruct the localization complex using

$$d(\lambda, m) = (\lambda, m/1), \quad \varepsilon(\lambda, m) = (\lambda, 0).$$

Its internal degree-zero cycles are exactly the reconstructed torsion module. Its internal first cohomology is the support skeleton, since the ordinary first cohomology vanishes. The map $p_{\mathbb{Z}}$ remains

in the structural coefficient square throughout; x is the analytic image of the operator $t - \rho$, not a replacement for the scalar e or τ .

The theorem does not assert $\mathcal{N} = 0$. It computes what local cohomology does to it: localization is an isomorphism on that module, so it contributes no cohomology to the stated local-support complex. Its possible contribution to a different global trace functor has not been declared absent.

S1.1.9 8. The residue duality is now inside an actual derived finite comparison

Assume the centres and their orders in h are stable under $\iota(s) = 1 - \bar{s}$. For germs define

$$f^\dagger(s) = \overline{f(1 - \bar{s})}.$$

The chosen monic polynomial satisfies $h^\dagger = (-1)^d h$. Retain that factor. Define the perfect finite algebra pairing

$$R_h(f, u) = \sum_i \operatorname{Res}_{s=\rho_i} \frac{f^\dagger(s)u(s)}{h(s)} ds.$$

It satisfies $\overline{R_h(u, f)} = (-1)^{d+1} R_h(f, u)$. No phase is inserted to change this sign. Since $g^\dagger = g$, multiplication by g_h is self-adjoint for this pairing. Therefore it induces a perfect pairing

$$\boxed{\overline{\operatorname{coker} g_h} \otimes \ker g_h \longrightarrow \mathbb{C}.$$

Well-definedness is the identity $R_h(ga, u) = R_h(a, gu)$; nondegeneracy follows by taking the annihilator of the image in the finite perfect algebra pairing. Through Section 4 this pairs the two actual cohomology groups of $C_+ \otimes_A^{\mathbf{L}} E_h$.

For an exact packet h_Z , set $v_{Z,h} = j_h(g/h_Z)$ as above and

$$j_Z : A_Z \rightarrow \ker g_h = E_Z, \quad [f] \mapsto [j_h(h_Z/g)f].$$

Here $A_Z = \prod_{\rho \in Z} \mathcal{O}_\rho / (g) \cong E_Z$ by the specified local quotient maps; h_Z/g is holomorphic at every centre. The local units are not replaced by one. The exact contraction is

$$\boxed{R_h(f, j_Z k) = \sum_{\rho \in Z} \operatorname{Res}_\rho \frac{f^\dagger k}{g} ds =: R_Z(f, k).$$

Thus the previously constructed arithmetic residue form is the duality pairing of the actual finite operator comparison after the displayed unit morphism.

The Jacobian map is still $J_g[k] = [g'k]$. Its contraction is

$$\boxed{R_h(f, j_Z J_g k) = R_Z(f, J_g k) = \sum_{\rho \in Z} r_\rho \overline{f(1 - \bar{\rho})} k(\rho) = \operatorname{Tr}(M_{f^\dagger k} | A_Z).$$

In particular the factor 2 in $g = 2\xi$ is retained in both the denominator and the Jacobian. The trace contraction is invariant under their combined explicitly specified transformation, not by deleting that factor in only one place.

Every map lifts to the original support fibres. Dual support arrows are precomposition maps on the opposite index category. A vanishing pairing value is the supported scalar $e_{\mathbb{C}}$; an absent argument gives τ .

S1.1.10 9. Cohomological placement and arithmetic traces

On the tau-base chart use the one-leg sheaf $\mathcal{T}_+$ and its A -action. The bounded projective resolution from TAU_BASE_MODEL.md gives the canonical map

$$\mathbf{A}_\tau(\mathcal{T}_+ \otimes_A^{\mathbf{L}} E_h) \xrightarrow{\sim} \mathbf{A}_\tau(\mathcal{T}_+) \otimes_A^{\mathbf{L}} E_h \xrightarrow{\sim} [E_h \xrightarrow{g_h} E_h].$$

These isomorphisms use finite evaluation sums and the displayed free/flat resolutions. They are not compact-support base-change assertions for a different arithmetic scheme.

The packet projector is now an actual finite-rank endomorphism of the original $H_\tau^1 = Q$ (and of each of its retained support fibres). For an admissible smooth compactly supported multiplicative test k ,

$$H_k F(x) = \int_0^\infty k(a) F(x/a) \frac{da}{a}$$

commutes with the projector. Its ordinary finite-rank trace is

$$\boxed{\mathrm{Tr}(H_k \Pi_Z | Q) = \sum_{\rho \in Z} r_\rho \mathcal{M}k(\rho).}$$

This is a finite-rank trace on the original cohomology, using its explicit finite invariant image. It is stronger than declaring that a surjective finite observation has a trace. Infinite trace summation still requires the specified topology and admissible test class.

On r -fold products over the tau-point, the already calculated external tensor map gives $H^r = Q^{\otimes r}$. The operator $\Pi_Z^{\otimes r}$ is a finite projector onto $Q[h_Z]^{\otimes r}$. The full nilpotent scaling action there is

$$a^{\rho_1 + \cdots + \rho_r} \exp \left((\log a) \sum_{j=1}^r N_{\rho_j, j} \right).$$

For a repeated exponent the exact modulus comparison remains

$$\log \frac{|a^{r\rho}|^2}{a^r} = r(2\Re\rho - 1) \log a.$$

This supplies actual finite invariant objects on which a Deligne-style tensor estimate would have to act. It does not prove that estimate. The source's opposite weight bounds, its global dualizing theory, and the admissibility of its geometric hypotheses have not been inferred from these finite isomorphisms.

S1.1.11 10. Status and publication boundary

Established in this note, with written proofs: the differential range identities on the stated spaces; the exact finite operator quotient and torsion kernel; the derived finite comparison; the analytic torsion-subsheaf and local-cohomology identification with $\mathcal{O}/(2\xi)$; finite spectral direct summands with explicit projectors; the original split lifts and smaller-label kernels; the residue/Jacobian contraction on that comparison; and compatible finite-rank arithmetic traces and tensor actions.

Not claimed: a global injectivity theorem for the full balanced analytic realization; vanishing of $\mathcal{R}_\infty$; identification of the entire four-point chart category with an arithmetic curve; a full compact-support/ordinary-cohomology realization satisfying the hypotheses of Weil II; positivity of the unshifted Weil form; RH or GRH. The finite tests are not a Lean or analytic proof certificate.

The prior base note and this continuation are published as additive research material beside PR #6. The original scalar core, formal modules, frozen reader and all existing branches remain unchanged. New derivations are AI-assisted work under the owner's programme; the structural source and its Lean implementation retain their own attribution. No copyrighted source corpus or private conversation is included.

S2.1 Chain-level arithmetic descent over the tau base

Owner-directed research continuation, 12 September 2026. Draft proofs for review; no new Lean certification or RH claim.

S2.1.1 0. Fixed inputs and publication scope

This is an additive continuation of Zeta PR #8 at 25689c5376166df37801229bc275ff5a896007d9, particularly workbenches/tau-base-cohomology/FINITE_OPERATOR_COMPARISON.md (Git blob 68f59d098d60708f8e899bb960abbd1135ebb3b4). Its sections 1–5 supply the stated analytic range theorem and the finite packet maps. The new result here is their chain-level descent, its actual extension class, and the connection of that class to residue duality and the arithmetic trace.

The source programme retains

$$G(R) = \{\tau\} \sqcup \{r^\bullet : r \in R\}, \quad e_R = 0_R^\bullet,$$

$$p_R(\tau) = 0_R, \quad p_R(r^\bullet) = r.$$

The absolute pointed base and the coefficient square remain

$$\mathfrak{b}_\tau = \operatorname{Spec} \mathbf{F}_{1,\tau}, \quad \begin{array}{ccc} G(\mathbb{Z}) & \xrightarrow{G(j)} & G(\mathbb{C}) \\ p_{\mathbb{Z}} \downarrow & & \downarrow p_{\mathbb{C}} \\ \mathbb{Z} & \xrightarrow{j} & \mathbb{C}. \end{array}$$

The target of the first vertical map remains the infinite ring of integers. Every new arrow below is a coefficient or cochain construction over this marked base. No base field, ideal norm, Euler factor, or completion constant is changed.

The supplied derived note and PR #6 provide `Recovery.recoverEquiv`, `Relations.coequalizer_universal`, the internal-homology coequalizer, `ChainMap.homologyKernelEquiv`, and `homology_int_ertwines`. Their algebraic conclusions are used at their stated types. No existing formal module is modified. Analytic inputs from PR #8 remain written research arguments; they are not promoted to Lean theorems.

S2.1.2 1. The actual arithmetic source and packet

Let

$$V = \{\phi \in \mathcal{S}(\mathbb{R}) : \phi(-x) = \phi(x), \phi(0) = 0, \int_{\mathbb{R}} \phi(x) dx = 0\},$$

$$\mathcal{B} = \{F \in C^\infty(\mathbb{R}_{>0}) : \sup_{x>0} x^b |(-x\partial_x)^k F(x)| < \infty \text{ for every } b \in \mathbb{Z}, k \geq 0\}.$$

Retain

$$D = -x\partial_x, \quad \Theta\phi(x) = \sum_{n \in \mathbb{Z} \setminus \{0\}} \phi(nx), \quad \mathcal{M}F(s) = \int_0^\infty F(x) x^s \frac{dx}{x},$$

$$\widehat{\phi}(\xi) = \int_{\mathbb{R}} \phi(x) e^{-2\pi i x \xi} dx, \quad A = \mathbb{C}[t], \quad t \cdot F = DF.$$

The one-leg tau-chart complex is

$$C_+ = [V \xrightarrow{\Theta} \mathcal{B}], \quad |V| = 0, \quad |\mathcal{B}| = 1, \quad Q = H^1(C_+).$$

The injectivity of theta gives $H^0(C_+) = 0$. The two-leg complex is

$$C_{+-} = [V \oplus V \longrightarrow \mathcal{B}], \quad (\phi, \psi) \mapsto \Theta\phi - \Theta\widehat{\psi}.$$

Its source operator is $(D, 1 - D)$; the inclusion $C_+ \rightarrow C_{+-}$ is $\phi \mapsto (\phi, 0)$ and the identity in degree one. It leaves the extra degree-zero copy of V in C_{+-} present.

Use the unchanged arithmetic multiplier

$$g(s) = 2\xi(s) = s(s-1)\pi^{-s/2}\Gamma(s/2)\zeta(s).$$

The input function is

$$\phi_*(x) = (4\pi^2 x^4 - 6\pi x^2) e^{-\pi x^2},$$

and the established identities are

$$\mathcal{M}\Theta\phi = gH_\phi, \quad H_{\phi_*} = 1, \quad H_{P(D)\phi_*}(s) = P(s).$$

Fix a nonempty finite packet Z of actual nontrivial zeros, with full orders m_ρ . Set

$$h(t) = \prod_{\rho \in Z} (t - \rho)^{m_\rho}, \quad d = \deg h, \quad E = A/(h), \quad v(s) = g(s)/h(s).$$

The specific monic polynomial defines this finite test; it does not rescale g . Write j_h for the complete Taylor-jet/Chinese-remainder map at these centres, and retain the invertible element

$$v_h = j_h v \in E^\times, \quad \varepsilon_Z = v_h^{-1}.$$

For $u \in E$, let $R_Z(u) \in \mathbb{C}[t]_{<d}$ be the unique polynomial representing $\varepsilon_Z u$.

The input range theorem supplies the inverse $S_h^{\mathcal{B}}$ of $h(D)$ on the zero-jet range, and the analogous source inverse S_h^V . For one factor,

$$S_\rho F(x) = x^{-\rho} \int_x^\infty F(y) y^{\rho-1} dy.$$

The stated source inverse uses $0 < \Re \rho < 1$ and the zero moment. Iteration supplies S_h . Define the actual maps

$$J : \mathcal{B} \rightarrow E, \quad JF = j_h \mathcal{M}F,$$

$$s : E \rightarrow \mathcal{B}, \quad s(u) = S_h^{\mathcal{B}} \Theta(R_Z(u)(D)\phi_*).$$

The inverse is defined because $gR_Z(u)$ has all required zero jets. Directly,

$$\mathcal{M}s(u) = vR_Z(u), \quad Js = 1_E, \quad J\Theta = 0, \quad h(D)s(u) = \Theta(R_Z(u)(D)\phi_*). \quad (1)$$

These equations fix the representative map, including all derivatives of g/h . On Q , the existing projector is $\Pi_Z = \bar{s}\bar{J}$, with image $Q[h(D)]$ and kernel $h(D)Q$.

S2.1.3 2. The exact equivariant extension and its class

Define an actual subspace of the original test-function space:

$$\mathcal{B}_Z = \{F \in \mathcal{B} : [F] \in Q[h(D)]\}.$$

Then

$$\mathcal{B}_Z = \Theta V \oplus s(E) \quad \text{as complex vector spaces,}$$

with maps

$$(\phi, u) \mapsto \Theta\phi + s(u), \quad F \mapsto (\Theta^{-1}(F - sJF), JF). \quad (2)$$

For the inverse, $F - sJF$ has zero class in Q by the packet projector theorem; injectivity of theta makes its source unique. The intersection is zero by $Js = 1$ and $J\Theta = 0$.

The original operator D preserves $\mathcal{B}_Z$, and there is a short exact sequence of A -modules

$$\boxed{0 \longrightarrow V \xrightarrow{\Theta} \mathcal{B}_Z \xrightarrow{J} E \longrightarrow 0.} \quad (3)$$

The arrows in (3), not just the three modules, specify its extension class. Compute it using the resolution

$$0 \longrightarrow A \xrightarrow{\times h} A \longrightarrow E \longrightarrow 0.$$

The resulting isomorphism $\text{Ext}_A^1(E, V) \cong V/h(D)V$ sends an extension to $h(D)b$ in the source, where b is any lift of $1 \in E$. Fixing this explicit rule fixes its sign. Under the existing map $[\phi] \mapsto j_h H_\phi$, the class of (3) is

$$\boxed{[\mathcal{B}_Z] = \varepsilon_Z = j_h(h/g) \in E^\times.} \quad (4)$$

Proof: use the lift $s(1)$ and (1). Its source boundary is $R_Z(1)(D)\phi_*$, whose H -jet is ε_Z .

In particular, (3) has no A -linear section. This also follows immediately from the injectivity of $h(D)$ on $\mathcal{B}$: an A -linear map $E \rightarrow \mathcal{B}$ has image killed by $h(D)$ and is therefore zero. The map s in (2) is the explicit complex-linear section, and the next section computes exactly how it fails to intertwine the arithmetic action. This non-splitting occurs for every nonempty packet, including critical-line packets; it is not an RH-failure criterion.

The general use of extension classes is standard homological algebra (Stacks, Tags 010I and 06XP). Formula (4) calculates the specific extension arising from this theta complex.

S2.1.4 3. The scaling defect is an original theta boundary

For $P \in A$ and $u \in E$, define

$$q_P(u) = \frac{P(t)R_Z(u) - R_Z(Pu)}{h(t)} \in A, \quad k_P(u) = q_P(u)(D)\phi_* \in V. \quad (5)$$

The numerator is divisible by h , since both of its residues are $P\varepsilon_Z u$. Using (1) and the injectivity of $h(D)$ on $\mathcal{B}$ gives

$$\boxed{P(D)s - sM_P = \Theta k_P.} \quad (6)$$

No quotient has yet been applied in (6). The right side is an actual theta function. The composition law is

$$\boxed{k_{PQ} = P(D)k_Q + k_P M_Q.} \quad (7)$$

It follows either by expanding the numerator of (5), or by expanding the commutator in (6) and using injectivity of theta.

For $P = t$, the numerator of (5) has degree at most d . Hence

$$\ell_Z(u) = [t^{d-1}]R_Z(u), \quad q_t(u) = \ell_Z(u), \quad \boxed{Ds(u) - s(tu) = \ell_Z(u)\Theta\phi_*} \quad (8)$$

Thus, in the exact coordinates (2), the original operator is

$$\boxed{D_{\mathcal{B}_Z} = \begin{pmatrix} D_V & \phi_*\ell_Z \\ 0 & M_t \end{pmatrix}.} \quad (9)$$

Its off-diagonal map is rank one and its coefficient is determined by the retained local arithmetic unit. It is not chosen to improve a spectral estimate.

For one simple zero,

$$h = t - \rho, \quad \varepsilon_Z = 1/g'(\rho),$$

$$s(1) = \frac{1}{g'(\rho)} x^{-\rho} \int_x^\infty \Theta\phi_*(y) y^{\rho-1} dy,$$

$$\boxed{(D - \rho)s(1) = \frac{1}{g'(\rho)} \Theta\phi_*} \quad (10)$$

The coefficient is $1/(2\xi'(\rho))$, with the original factor two retained.

The full dilation group For $a > 0$, retain $U_a F(x) = F(x/a)$ and $A_a = M_{j_h(a^s)}$ on E . Define

$$k_a(u) = S_h^V (U_a(R_Z(u)(D)\phi_*) - R_Z(A_a u)(D)\phi_*). \quad (11)$$

The source of S_h^V has zero H -jets because $a^s \varepsilon_Z u$ and $\varepsilon_Z A_a u$ have equal jets. All powers use the real logarithm of a . The exact identities are

$$U_a s - s A_a = \Theta k_a, \quad k_{ab} = U_a k_b + k_a A_b, \quad k_1 = 0. \quad (12)$$

The same construction applies to a smooth compactly supported multiplicative test f : replace U_a by $H_f = \int f(a) U_a da/a$ and A_a by $M_{j_h \mathcal{M} f}$. The source integral belongs to V ; its H -jets give the same cancellation. These are actual linear maps, not a choice of a formal matrix on E alone.

S2.1.5 4. A derived equivariant inclusion with its full homotopy

Put $P_Z = sJ : \mathcal{B} \rightarrow \mathcal{B}$. It is a finite-rank idempotent, and $P_Z\Theta = 0$. Consequently

$$\mathfrak{p}_Z = (0, P_Z) : C_+ \rightarrow C_+ \quad (13)$$

is a cochain idempotent. Its image is the two-term complex $[0 \rightarrow s(E)]$, complex-linearly isomorphic to $E[-1]$.

For the operator $P(D)$ on C_+ , define a degree-minus-one map with sole component

$$\mathbf{H}_P^1 = k_P J : \mathcal{B} \rightarrow V.$$

Equation (6) gives

$$\boxed{P(D)\mathfrak{p}_Z - \mathfrak{p}_Z P(D) = d\mathbf{H}_P + \mathbf{H}_P d.} \quad (14)$$

In degree one this is $\Theta k_P J$; in degree zero it is zero because $J\Theta = 0$. For dilation use $\mathbf{H}_a^1 = k_a J$. Equation (12) is the coherence law of those homotopies.

There is also a strictly A -linear derived presentation. Set

$$C_Z = [V \xrightarrow{\Theta} \mathcal{B}_Z].$$

In the coordinates (2) its differential is $\phi \mapsto (\phi, 0)$ and its action is (9). The maps

$$\iota : C_Z \hookrightarrow C_+, \quad \pi : C_Z \rightarrow E[-1], \quad \pi^0 = 0, \pi^1 = J \quad (15)$$

are strictly A -linear cochain maps, and π is a quasi-isomorphism. Thus the actual equivariant inclusion is the roof

$$\boxed{E[-1] \xleftarrow[\simeq]{\pi} C_Z \xrightarrow{\iota} C_+.} \quad (16)$$

The complex-linear deformation retraction also has an exact contracting homotopy: on $\mathcal{B}_Z$, send $\Theta\phi + s(u)$ to $\phi \in V$. Its equation is $1 - s\pi = dH + Hd$ (with s interpreted as the degree-one cochain section). This homotopy is not claimed A -linear; the A -linear replacement is the roof (16).

The strictly A -linear map $j : C_+ \rightarrow E[-1]$ is J in degree one and zero in degree zero. It satisfies $j\iota = \pi$. This gives a split retract in $D(A)$ without falsely asserting an A -linear section into $\mathcal{B}$.

On the two-leg complex use $\mathfrak{p}_Z^0 = 0$ on $V \oplus V$, $\mathfrak{p}_Z^1 = P_Z$, and $\mathbf{H}_a^1(F) = (k_a JF, 0)$. The source dilation is $(U_a, aU_{1/a})$, so (14) holds with its original two-leg differential. The inclusion $C_+ \rightarrow C_{+-}$ commutes with these cochain projectors. The extra degree-zero cohomology of C_{+-} is killed by this projector; it remains in the complementary complex.

S2.1.6 5. The mixed-support homotopies require the actual synchronization map

Let $L = \mathcal{P}(\{+, -\})$ be the original chart-support lattice. Its three active complexes are

$$C_+ = [V \xrightarrow{\Theta} \mathcal{B}], \quad C_- = [V \xrightarrow{-\Theta\mathcal{F}} \mathcal{B}], \quad C_{+-} = [V \oplus V \xrightarrow{\Theta(\phi - \hat{\psi})} \mathcal{B}].$$

Here $\mathcal{F}$ is the specified Fourier transform, with $\mathcal{F}^2 = 1$ on even functions. The source inclusions into the joint fibre are $v \mapsto (v, 0)$ and $v \mapsto (0, v)$; degree-one transports are identities. The bottom complex is zero in this particular model. The new formalization allows a nonzero bottom fibre in the general reconstruction; no assertion about all diagrams is obtained by specializing this model.

The reconstructed operations are

$$(\lambda, x) + (\mu, y) = (\lambda \vee \mu, \rho_{\lambda, \lambda \vee \mu} x + \rho_{\mu, \lambda \vee \mu} y),$$

$$e(\lambda, x) = (\lambda, 0), \quad \tau(\lambda, x) = (\perp, 0). \quad (17)$$

The cochain projector $\tilde{p}_Z$ is zero-in-its-fibre in degree zero and P_Z in degree one. It commutes with the support transports. So does the actual action: U_a on the plus source, $aU_{1/a}$ on the minus source, their direct sum on the joint source, and U_a at every active overlap.

The objectwise homotopies are, however, different maps. With $b = k_a JF$, they are

$$H_{a,+}^1(F) = b, \quad H_{a,-}^1(F) = -\hat{b}.$$

Their images in the joint source are $(b, 0)$ and $(0, -\hat{b})$. The difference is the explicit cycle

$$(b, \hat{b}) \in \ker d_{+-} = H^0(C_{+-}). \quad (18)$$

For nonzero k_a , there is no label-preserving family of homotopies compatible with both source inclusions: the joint component would have to equal both $(b, 0)$ and $(0, -\hat{b})$. This says exactly which naturality square fails. It does not discard the cohomology or the arithmetic action.

The replacement is the programme's actual synchronization. Define the support map

$$r_L(\perp) = \perp, \quad r_L(\lambda) = \{+, -\} \quad (\lambda \neq \perp).$$

In degree zero use literal multiplication by $E = (1, e)$ on the original two-coordinate support module:

$$\mathfrak{r}^0(a, b) = (a + eb, b + ea).$$

In degree one define $\mathfrak{r}^1(\lambda, F) = (r_L \lambda, F)$ for active labels and preserve global zero. An absent source coordinate becomes its supported vector zero, so the source differential has unchanged amplitude. Hence

$$d\mathfrak{r}^0 = \mathfrak{r}^1 d, \quad \mathfrak{r}^2 = \mathfrak{r}. \quad (19)$$

This uses the operation verified in the synchronization attachment, now on the actual complex. The fixed active fibre is exactly C_{+-} . On degree-one homology, the map is

$$(\lambda, [F]) \mapsto (\{+, -\}, [F]).$$

It has no nonzero amplitude kernel, because all degree-one transports are the identity of Q . The original mask is retained through

$$x \mapsto (\text{supp}(x), \mathfrak{r}x).$$

This map is injective in each degree of this chart complex: in degree zero the coordinate inclusions are injective, and in degree one the transport is the identity. This injectivity is a proved property of these maps, not an assumption for general diagrams with noninjective transports.

There are now two actual split-linear homotopies with the same support map r_L . Define

$$\tilde{H}_a^{\text{left},1}(\lambda, F) = (\{+, -\}, (k_a JF, 0)),$$

$$\tilde{H}_a^{\text{right},1}(\lambda, F) = (\{+, -\}, (0, -\mathcal{F}k_a JF)),$$

and send global zero to global zero. Both satisfy

$$\tau(\tilde{U}_a \tilde{p}_Z + (-1)^{\bullet} \tilde{p}_Z \tilde{U}_a) = \tilde{d} \tilde{H}_a + \tilde{H}_a \tilde{d}. \quad (20)$$

In degree one this is (6); in degree zero it follows from $Jd = 0$. The two choices differ by the retained cycle (18). No averaging or removal of that cycle is performed. This is the precise role of synchronization here: it permits a common supported comparison fibre for the homotopy, while the original mask and the difference of homotopies remain recorded.

In the simple-zero case (10), the defect in any source support is the nonzero chain amplitude $\Theta(\phi_*/g'(\rho))$. Its internal homology class is the zero of that support, not external absence.

For every chain comparison $f : C \rightarrow C'$, the supplied formalized kernel equivalence remains

$$\{z \in Z(C) : f(z) \in B(C')\} / B(C) \xrightarrow{\sim} \ker H(f).$$

Applied to π in (15), it computes the zero kernel in degree one from its actual exact sequence. Applied to support synchronization, it yields the degree-one assertion just proved and the separately retained degree-zero data. It is not applied to a different global comparison without carrying that comparison's maps.

For any smaller D -stable admitted source $W \subset V$, the map $Q_W \rightarrow Q$ has kernel $\Theta V / \Theta W$. A homotopy value may not already lie in W . The explicit replacement is enlargement by the actual source values, with this quotient map and its kernel retained. The present chart uses full V , where every displayed homotopy is defined.

S2.1.7 6. The same extension class produces the arithmetic duality factor

Assume Z is stable under $\rho \mapsto 1 - \bar{\rho}$. Then

$$f^\dagger(s) = \overline{f(1 - \bar{s})}, \quad h^\dagger = (-1)^d h.$$

The perfect finite pairing is

$$R_h(f, u) = \sum_{\rho \in Z} \text{Res}_{s=\rho} \frac{f^\dagger(s) u(s)}{h(s)} ds,$$

with exact symmetry $\overline{R_h(u, f)} = (-1)^{d+1} R_h(f, u)$.

Identify E with the actual divisor algebra $A_Z = \prod_{\rho \in Z} \mathcal{O}_\rho / (g)$ by polynomial evaluation and the complete Chinese-remainder jets. The nonzero local units in g/h make this an isomorphism. The operator represented by the extension class is

$$M_{\varepsilon_Z} : E \rightarrow E.$$

Substituting (4) into the residue formula gives

$$R_h(f, M_{\varepsilon_Z} u) = \sum_{\rho \in Z} \text{Res}_\rho \frac{f^\dagger u}{g} ds = R_Z(f, u). \quad (21)$$

This is independent of representatives: changing ε_Z by h times a germ adds a holomorphic differential. Thus the actual extension class is precisely the unit morphism converting the polynomial-resolution residue form into the arithmetic residue form.

Let $J_g = M_{j_h g'}$. Then

$$R_h(f, M_{\varepsilon_Z} J_g u) = \sum_{\rho \in Z} m_\rho \overline{f(1 - \bar{\rho})} u(\rho) = \text{Tr}(M_{f^\dagger u} \mid E). \quad (22)$$

Locally $g = z^m w(z)$ gives $g'/g = m/z + w'/w$. This proves the formula and retains every multiplicity. The product $\varepsilon_Z J_g$ carries both factors associated to $g = 2\xi$.

The pairing-valued support map sends a zero value to $e_{\mathbb{C}}$ and an absent argument to τ . Its original input support and relation fibre remain available upstream. Formula (22) is a calculated trace, not a positivity assertion.

Reflection is strict for this specified section Define conjugate-linear involutions

$$j_B F(x) = x^{-1} \overline{F(1/x)}, \quad j_V \phi = \widehat{\phi}, \quad j_E u = u^\dagger.$$

They satisfy $\Theta j_V = j_B \Theta$ and $J j_B = j_E J$. The actual source function is Fourier-fixed: writing $\phi_* = D(D-1)e^{-\pi x^2}$, Fourier sends the two factors to $(1-D)(-D) = D(D-1)$ and fixes the Gaussian. It is real, so $j_V \phi_* = \phi_*$.

Since $\varepsilon_Z^\dagger = (-1)^d \varepsilon_Z$ and reflection preserves polynomial degree,

$$R_Z(j_E u) = (-1)^d (R_Z(u))^\dagger.$$

Uniqueness of the inverse of $h(D)$ on its range gives

$$j_B S_h^{\mathcal{B}} = (-1)^d S_h^{\mathcal{B}} j_B.$$

Both factors $(-1)^d$ are retained in the substitution, and their product is one. Therefore

$$j_B s = s j_E, \quad j_B P_Z = P_Z j_B. \quad (23)$$

This is an actual equality for this section; it would not follow for an arbitrary choice of representatives. Its compatibility with the nonzero dilation homotopy is

$$j_V k_a = a k_{1/a} j_E. \quad (24)$$

Indeed, apply j_B to (12), use $j_B U_a = a U_{1/a} j_B$ and (23), then use injectivity of theta. The split lift is semilinear through $r^\bullet \mapsto \bar{r}^\bullet$, which fixes both e and τ .

S2.1.8 7. A finite-rank Lefschetz trace on the actual chain complex

For $f \in C_c^\infty(\mathbb{R}_{>0})$, let U_f be its convolution action on C_+ . The cochain endomorphism

$$p_Z U_f = (0, s J H_f)$$

has finite-rank components. Its cochain supertrace is therefore defined without an infinite-dimensional regularization:

$$\text{Str}(p_Z U_f \mid C_+) = -\text{Tr}(s J H_f \mid \mathcal{B}) = -\sum_{\rho \in Z} m_\rho \mathcal{M}f(\rho). \quad (25)$$

The finite-rank identity $\text{Tr}(AB) = \text{Tr}(BA)$ reduces the middle expression to $\text{Tr}(J H_f s \mid E)$; this is multiplication by $j_h \mathcal{M}f$. Equation (25) equals the supertrace of the induced operator on homology.

On C_{+-} its degree-zero contribution is still zero, since the same cochain projector has zero degree-zero component.

The boundary representatives in (6), (14), and (20) are retained even though their contribution to homology is zero. The finite-rank trace does not delete their complex or assign its zero to external absence.

For the n -fold tensor complex over the tau-base product, use the original coefficient tensor over $\mathbb{C}$ and its differential

$$d(x_1 \otimes \cdots \otimes x_n) = \sum_j (-1)^{\sum_{i < j} |x_i|} x_1 \otimes \cdots \otimes dx_j \otimes \cdots \otimes x_n.$$

The projector $\mathfrak{p}_Z^{\otimes n}$ has image $E^{\otimes n}[-n]$. For independently specified tests $f_1, \dots, f_n$,

$$\text{Str} \left(\bigotimes_j (\mathfrak{p}_Z \cup_{f_j}) \right) = (-1)^n \prod_j \sum_{\rho \in Z} m_\rho \mathcal{M} f_j(\rho). \quad (26)$$

Let $A = U_a \mathfrak{p}_Z$ and $B = \mathfrak{p}_Z U_a$ as cochain maps. A homotopy for $A^{\otimes n} - B^{\otimes n}$ is

$$\sum_{j=1}^n B^{\otimes(j-1)} \otimes H_a \otimes A^{\otimes(n-j)},$$

with the displayed Koszul sign on homogeneous inputs when the degree-minus-one map crosses the preceding factors. The telescoping identity and (14) prove it. The full support mask maps to the product of its input masks; vanishing products of represented amplitudes stay supported.

S2.1.9 8. What now enters the Weil II programme

The structural base, the infinite quotient, and the actual theta complex are unchanged. The new objects are the extension (3), its unit class (4), its synchronized homotopy (20), its strict equivariant derived roof (16), and the chain trace (25). The arithmetic residue unit in (21) is now supplied by that very extension rather than appended without its source.

Deligne's inspected comparison-image argument (Weil II 3.3.4–3.3.6) requires two weight bounds on the same cohomological image. The inspected derived formulation (6.2.1–6.2.7) retains the dualizing operation, its degree and Tate shifts, and its exchange of direct-image functors. This continuation supplies coherent arithmetic maps and finite trace operations for the tau model; it does not transfer the finite-field hypotheses or assert those two bounds.

The retained error is explicit: it is the original boundary Θ_{k_a} on representatives, with the nonzero Ext class (4). It is removed at homology by the original supported quotient, not by making its input absent. A geometric comparison can now be tested for compatibility with this class and the residue map (21). A complex-linear section that ignores (6) fails that test.

No infinite sum of packet projectors is asserted to converge. The existing meromorphic/kernel summand from PR #8 remains in its own exact sequence, and a different global trace functor must retain or analyze its contribution. The source's finite-jet isomorphisms and the new finite-rank chain trace do not by themselves set that summand to zero.

S2.1.10 9. Verification and references

The new finite checker tests polynomial remainder identities, the extension class, rank-one scaling defects, cochain homotopies, dilation cocycles, residue contraction, tensor signs, trace identities, and

original support operations. These finite algebraic models are not numerical tests of zeta zeros and not certificates for the analytic range theorem. No Lean execution is claimed for this continuation.

S3.1 A global retraction of the original theta complex over the tau base

Owner-directed continuation of Zeta PR #9, 12 September 2026. New derivations are submitted as research proofs for review, not as Lean-certified analytic theorems.

S3.1.1 0. Fixed source, result, and provenance

The base is PR #9 at 8f99b94d306c3b1aaa817d52c57fa6fd298d511c; its chain-descent note has Git blob 86db838e79d10a8fe7d4376303706c4ea64570a1. Its source and the owner's derived SplitZero attachment remain the inputs. This continuation constructs an inverse on the entire original theta image, not only on a chosen finite spectral packet.

Retain

$$G(R) = \{\tau\} \sqcup \{r^\bullet : r \in R\}, \quad e_R = 0_R^\bullet,$$

$$\mathfrak{b}_\tau = \operatorname{Spec} \mathbf{F}_{1,\tau}, \quad \begin{array}{ccc} G(\mathbb{Z}) & \xrightarrow{G(j)} & G(\mathbb{C}) \\ p\mathbb{Z} \downarrow & & \downarrow p\mathbb{C} \\ \mathbb{Z} & \xrightarrow{j} & \mathbb{C}. \end{array} \quad (1)$$

The first vertical target is still infinite. The geometric base, the original additive laws, and the arithmetic quotient are unchanged. The auxiliary cutoffs below are parameters of an explicit continuous representative map; they do not change an Euler factor, the theta relation space, or the completed zeta function.

Result. For every pair of the cutoffs specified in section 3 there is an explicitly constructed continuous complex-linear map

$$\Lambda_{\alpha,\beta} : \mathcal{B} \longrightarrow V, \quad \boxed{\Lambda_{\alpha,\beta}\Theta = \operatorname{id}_V}. \quad (2)$$

Consequently the actual image ΘV is closed and complemented in the stated strong-Schwartz topology. The original quotient $Q = \mathcal{B}/\Theta V$ is Hausdorff. The note constructs its global section, the full supported cochain homotopy, the exact change of the finite sections in #9, its continuous dual sequence, and the completed tensor powers. The proof does not assume RH, simplicity of any zero, or vanishing of the separate balanced-Mellin kernel.

Spectral realizations on nuclear Frechet spaces are prior work, notably R. Meyer, arXiv:math/0412277. That paper's abstract was consulted for scope, but no theorem from an unread body of that paper is imported. The proof below is given for the workbench's precise spaces. No global novelty claim is made.

S3.1.2 1. Spaces and all transforms

Let

$$V = \{\phi \in \mathcal{S}(\mathbb{R}) : \phi(-x) = \phi(x), \phi(0) = 0, \int_{\mathbb{R}} \phi(x) dx = 0\},$$

$$\mathcal{B} = \{F \in C^\infty(\mathbb{R}_{>0}) : p_{b,k}(F) := \sup_{x>0} x^b |D^k F(x)| < \infty \text{ for every } b \in \mathbb{Z}, k \geq 0\}, \quad D = -x\partial_x. \quad (3)$$

These seminorms give $\mathcal{B}$ its Frechet topology; under $x = e^y$ they are the weighted uniform derivative seminorms on smooth functions of y . Completeness follows by uniform convergence on compact sets of every derivative, followed by the weighted bounds. V has its closed-subspace Schwartz topology.

The original maps are

$$\begin{aligned} \Theta\phi(x) &= \sum_{n \in \mathbb{Z} \setminus \{0\}} \phi(nx) = 2 \sum_{n \geq 1} \phi(nx), \\ \mathcal{F}\phi(\xi) &= \int_{\mathbb{R}} \phi(x) e^{-2\pi i x \xi} dx, \quad \mathcal{F}^{-1}u(x) = \int_{\mathbb{R}} u(\xi) e^{2\pi i x \xi} d\xi, \\ JF(x) &= x^{-1}F(1/x), \quad \mathcal{M}F(s) = \int_0^\infty F(x) x^s \frac{dx}{x}. \end{aligned} \quad (4)$$

Poisson summation, with both source moments zero, gives

$$\Theta\mathcal{F} = J\Theta, \quad J^2 = 1, \quad DJ = J(1 - D). \quad (5)$$

The theta sum and each derivative converge absolutely on closed subsets of $x > 0$. At infinity, Schwartz estimates give all $p_{b,k}$ bounds. At zero use (5) and the same estimates on $\hat{\phi}$. This proves continuity $\Theta : V \rightarrow \mathcal{B}$. Also J is continuous on $\mathcal{B}$: $p_{b,k}(JF)$ is bounded by the binomial sum of $p_{1-b,j}(F)$, $0 \leq j \leq k$.

The original complex is $C_+ = [V \xrightarrow{\Theta} \mathcal{B}]$ in degrees 0, 1, over $A = \mathbb{C}[t]$ with t acting as D . The two-leg tau chart retains $C_{+-} = [V^2 \rightarrow \mathcal{B}]$ with differential $\Theta(\phi - \hat{\psi})$ and source action $(D, 1 - D)$.

S3.1.3 2. Arithmetic inversion on the two exterior regions

Let μ be the ordinary Mobius function, characterized by

$$\sum_{d|n} \mu(d) = \begin{cases} 1, & n = 1, \\ 0, & n > 1. \end{cases}$$

For $F \in \mathcal{B}$ define, for $x \neq 0$,

$$\boxed{\mathcal{U}F(x) = \frac{1}{2} \sum_{n \geq 1} \mu(n) F(n|x|)}. \quad (6)$$

The factor $1/2$ is the inverse of the full nonzero-integer theta sum in (4). The map is complex-linear into smooth even functions on $\mathbb{R} \setminus \{0\}$. It is not asserted to be smooth at zero for arbitrary F .

Here are the required estimates. For $j \geq 0$, let $P_j(T) = (-1)^j T(T+1) \cdots (T+j-1)$, with $P_0 = 1$. Then $x^j \partial_x^j = P_j(D)$. If $C_{N,j}(F)$ is the sum of the $p_{N,k}(F)$ weighted by the absolute coefficients of P_j , then, for $x > 0$ and integer $N > 1$,

$$|\partial_x^j \mathcal{U}F(x)| \leq \frac{1}{2} \zeta(N) C_{N,j}(F) x^{-N-j}. \quad (7)$$

Indeed each summand is bounded by $C_{N,j}(F) n^{-N} x^{-N-j}/2$. This proves convergence of every derivative uniformly for $|x| \geq \delta > 0$, and gives rapid decay there. It also proves continuity of the cut-off exterior maps used below.

For every $\phi \in V$,

$$\boxed{\mathcal{U}\Theta\phi(x) = \phi(x), \quad \mathcal{U}J\Theta\phi(x) = \widehat{\phi}(x) \quad (x \neq 0).} \quad (8)$$

For the first equality the double series is absolutely convergent for each $x > 0$: its absolute value is bounded by $\sum_{k \geq 1} d(k) |\phi(kx)|$, which is finite by Schwartz decay. Rearrange by $k = mn$ and use the displayed divisor identity. Evenness handles negative x . The second equality follows from (5) and the first equality applied to $\widehat{\phi} \in V$.

In the split lift, every $\mu(n)$ is the supported integer $\mu(n)^\bullet$, including $\mu(n) = 0$. A convergent sum within a specified active fibre begins at that fibre's zero and is taken in that fibre's vector-space topology. Formula (8) thus lifts to a support-preserving equality. A computed cancellation is not external absence.

S3.1.4 3. The reconstruction operator, with the strict contraction proved

Choose and retain real, even $\alpha, \beta \in C_c^\infty(\mathbb{R})$ satisfying $0 \leq \alpha, \beta \leq 1$ and equal to 1 on neighborhoods of zero. Their supports and all values are part of the auxiliary data. Work on $\mathcal{H} = L^2(\mathbb{R}, dx)$ with the Fourier convention in (4).

Define bounded operators

$$A_\alpha = M_\alpha, \quad B_\beta = \mathcal{F}^{-1} M_\beta \mathcal{F}, \quad T_{\alpha,\beta} = A_\alpha B_\beta. \quad (9)$$

Lemma. $T_{\alpha,\beta}$ is compact and $c_{\alpha,\beta} := \|T_{\alpha,\beta}\| < 1$.

Proof. Its kernel is $\alpha(x)\check{\beta}(x-y)$, whose squared integral is $\|\alpha\|_2^2 \|\beta\|_2^2$. Hence it is Hilbert-Schmidt. Both factors are contractions. If the norm were 1, compactness would supply a unit vector f attaining it. Equality in

$$\|A_\alpha B_\beta f\| \leq \|B_\beta f\| \leq \|f\|$$

forces $\widehat{f}$ to be supported where $\beta = 1$; there $B_\beta f = f$. The first equality forces f to be supported where $\alpha = 1$. Both supports are compact. The inverse Fourier transform of compactly supported $\widehat{f} \in L^2$ is entire, by differentiation under its finite-interval integral. Its continuous restriction agrees with the compactly supported f , so it vanishes on an open real interval and hence identically. This contradicts $\|f\| = 1$. Thus $c_{\alpha,\beta} < 1$.

Consequently the exact Neumann inverse exists:

$$\boxed{(1 - T_{\alpha,\beta})^{-1} = \sum_{k \geq 0} T_{\alpha,\beta}^k, \quad \|(1 - T_{\alpha,\beta})^{-1}\| \leq \frac{1}{1 - c_{\alpha,\beta}}.} \quad (10)$$

No uniform bound as the cutoffs vary is claimed. In particular the gap $1 - c_{\alpha,\beta}$ is retained, not replaced by a positive universal constant.

The operator $T_{\alpha,\beta}$ maps L^2 continuously to the Schwartz space. For each derivative, compact Fourier support and Cauchy-Schwarz bound $\partial^j B_\beta f$ uniformly by a constant times $\|f\|_2$; multiplication by the smooth compactly supported α gives every Schwartz seminorm.

Define the two exterior data and their combination:

$$a_F = (1 - \alpha)\mathcal{U}F, \quad b_F = (1 - \beta)\mathcal{U}JF,$$

$$Y_{\alpha,\beta}F = a_F + \alpha\mathcal{F}^{-1}b_F. \quad (11)$$

The exterior terms are extended by zero near the origin, where their cutoff is identically zero. Estimates (7) prove that both are even Schwartz functions and depend continuously on F . Therefore $Y : \mathcal{B} \rightarrow \mathcal{S}(\mathbb{R})^{\text{even}}$ is continuous.

Put

$$\Phi_{\alpha,\beta}F = (1 - T_{\alpha,\beta})^{-1}Y_{\alpha,\beta}F. \quad (12)$$

This initially defines an L^2 vector, but the identity $\Phi F = YF + T\Phi F$ proves it is Schwartz. If q is any Schwartz seminorm and $q(Tu) \leq C_q\|u\|_2$, then

$$q(\Phi F) \leq q(YF) + \frac{C_q}{1 - c_{\alpha,\beta}}\|YF\|_2. \quad (13)$$

This is an explicit continuity estimate. Both sides are even because the cutoff operators preserve parity.

For $F = \Theta\phi$, equations (8) give

$$Y\Theta\phi = (1 - A_\alpha)\phi + A_\alpha(1 - B_\beta)\phi = (1 - T_{\alpha,\beta})\phi,$$

hence

$$\boxed{\Phi_{\alpha,\beta}\Theta\phi = \phi.} \quad (14)$$

S3.1.5 4. Keep both original moment conditions

For arbitrary F , (12) need not satisfy the two source moments. The correction is the following specified projection, not an alteration of V .

Retain

$$\gamma_0(x) = e^{-\pi x^2}, \quad \gamma_2(x) = 2\pi x^2 e^{-\pi x^2}.$$

Their moment columns $(\phi(0), \int \phi)$ are $(1, 1)$ and $(0, 1)$. Define

$$\mathbf{m}(\phi) = (\phi(0), \int_{\mathbb{R}} \phi), \quad j_0(a, b) = a\gamma_0 + (b - a)\gamma_2,$$

$$P_V\phi = \phi - j_0\mathbf{m}(\phi) = \phi - \phi(0)\gamma_0 - \left(\int \phi - \phi(0)\right)\gamma_2. \quad (15)$$

Then $\mathbf{m}j_0 = 1$, $P_V^2 = P_V$, $\text{im } P_V = V$, and $P_V|_V = 1$. All maps are continuous.

The promised map is

$$\boxed{\Lambda_{\alpha,\beta} = P_V(1 - T_{\alpha,\beta})^{-1}Y_{\alpha,\beta} : \mathcal{B} \rightarrow V.} \quad (16)$$

Equation (14) and $P_V|_V = 1$ prove (2). The discarded moment vector has the recorded map $m\Phi : \mathcal{B} \rightarrow \mathbb{C}^2$ and the explicit correction $j_0 m\Phi$. It vanishes on the actual theta image. No endpoint constant was absorbed into the zeta function.

S3.1.6 5. The full quotient is closed and has a continuous section

Write $\Lambda = \Lambda_{\alpha,\beta}$, and define

$$P_\Theta = \Theta\Lambda, \quad K = 1_{\mathcal{B}} - \Theta\Lambda. \quad (17)$$

Direct substitution gives

$$P_\Theta^2 = P_\Theta, \quad K^2 = K, \quad \ker K = \Theta V, \quad \text{im } K = \ker \Lambda. \quad (18)$$

Since K is continuous, its kernel is closed. Thus $Q = \mathcal{B}/\Theta V$ with its actual quotient topology is Frechet and Hausdorff. If $q : \mathcal{B} \rightarrow Q$ is the original quotient map, the continuous section is

$$\boxed{s : Q \rightarrow \mathcal{B}, \quad s[F] = KF, \quad qs = 1, \quad \Lambda s = 0.} \quad (19)$$

The explicit topological direct-sum isomorphism is

$$\boxed{V \oplus Q \xrightarrow{\sim} \mathcal{B}, \quad (\phi, u) \mapsto \Theta\phi + su, \quad F \mapsto (\Lambda F, qF).} \quad (20)$$

For a convergent sequence $\Theta\phi_n \rightarrow F$ in $\mathcal{B}$, one can check the closedness without any abstract theorem: $\phi_n = \Lambda\Theta\phi_n \rightarrow \Lambda F$ in V , so $F = \Theta\Lambda F$ by continuity of theta.

This computes the earlier Hausdorff arrow:

$$Q^{\text{alg}} = \mathcal{B}/\Theta V \longrightarrow Q^{\text{H}} = \mathcal{B}/\overline{\Theta V}, \quad [F] \mapsto [F], \quad (21)$$

as an isomorphism with zero amplitude kernel. It does not say the map from Q into its product of spectral jets is injective. The latter map and the balanced analytic map still have their own named kernels:

$$Q \rightarrow \prod_{\rho} \mathcal{O}_{\rho}/(g), \quad \mathcal{O} \otimes_{\mathbb{C}[t]} Q \xrightarrow{\beta} \mathcal{O}/(g).$$

No claim that $\mathcal{R}_{\infty}$ or $\ker \beta$ vanishes is inferred from (21).

Smaller admitted relations For any specified subspace $W \subset V$, retain

$$Q_W = \mathcal{B}/\Theta W \longrightarrow Q, \quad \ker = \Theta V/\Theta W \cong V/W. \quad (22)$$

The isomorphism sends $[\phi] \mapsto [\Theta\phi]$. It is algebraic for arbitrary W ; when W is closed, (20) makes it a topological isomorphism onto the kernel. The pullback of the global section has the representative relation kernel in (22); the full-source result is not silently asserted with W in place of V .

S3.1.7 6. Perform the original internal quotient and synchronization

On the single-leg map, or a fixed-index diagram of that same map, the split lifts are

$$\tilde{\Theta}(\lambda, \phi) = (\lambda, \Theta\phi), \quad \tilde{\Lambda}(\lambda, F) = (\lambda, \Lambda F), \quad \tilde{K}(\lambda, F) = (\lambda, KF). \quad (23)$$

They preserve external bottom and commute with scalar reflection. In particular

$$\tilde{K}\tilde{\Theta}(\lambda, \phi) = (\lambda, 0_{\mathcal{B}}) = z_{V, \mathcal{B}}(\lambda, \phi).$$

Here $z_{V, \mathcal{B}}$ is the label-preserving zero map from the source fibre to the target fibre. The mixed chart, whose minus restriction is $-\Theta\mathcal{F}$, is treated separately by the explicit maps (25)-(28), without changing that restriction. The actual chart has zero bottom fibre; a general nonzero bottom fibre is acted on by its stated linear map, rather than identified with the single global zero.

The supported image projection is idempotent, and the quotient map is exactly the coequalizer of the theta relation inclusion and its supported-zero companion. The implementation's universal property applies against all split-linear targets. A theta boundary is sent to $e_\lambda = (\lambda, 0)$; it is not sent to external absence.

For the single-leg complex there is an actual continuous contraction

$$C_+ \xrightleftharpoons[s]{q} Q[-1], \quad H^1 = \Lambda,$$

$$\boxed{qs = 1, \quad 1_{C_+} - sq = dH + Hd.} \quad (24)$$

In degree zero this is $\Lambda\Theta = 1_V$; in degree one it is $\Theta\Lambda = 1 - K$. In split notation the subtraction means addition of the supported scalar $(-1)^\bullet$ times the second map. It yields the correct labelled zero wherever the amplitude vanishes.

For the two-leg chart set $H_0 = V[0] \oplus Q[-1]$ with zero differential, and define

$$p_L^0(\phi, \psi) = \psi, \quad p_L^1 = q, \quad i^0(\psi) = (\hat{\psi}, \psi), \quad i^1 = s,$$

$$H_L^1(F) = (\Lambda F, 0). \quad (25)$$

Then $p_L i = 1$, and $1 - ip_L = dH_L + H_L d$. The degree-zero identity is $(\phi, \psi) - (\hat{\psi}, \psi) = (\phi - \hat{\psi}, 0)$. The other leg gives

$$p_R^0(\phi, \psi) = \hat{\phi}, \quad p_R^1 = q, \quad H_R^1(F) = (0, -\widehat{\Lambda F}). \quad (26)$$

It obeys $1 - ip_R = dH_R + H_R d$. Their homotopies differ by

$$\boxed{H_L^1 F - H_R^1 F = (\Lambda F, \widehat{\Lambda F}),} \quad (27)$$

the actual joint degree-zero cycle, which is retained.

On the complete original support diagram, use literal multiplication by $E_{\text{sync}} = (1, e)$ in degree zero and the source's active-label-to-joint map in degree one:

$$\mathfrak{r}^0(a, b) = (a + eb, b + ea), \quad \mathfrak{r}^1(\lambda, F) = (\{+, -\}, F) \quad (\lambda \neq \perp).$$

The absent input remains absent. The original differential obeys $d\mathfrak{r} = \mathfrak{r}d$ and $\mathfrak{r}^2 = \mathfrak{r}$. Consequently (25) lifts to the fully typed equation

$$\mathfrak{r} - \tilde{i}\tilde{p}_L\mathfrak{r} = \tilde{d}\tilde{H}_L + \tilde{H}_L\tilde{d}, \quad (28)$$

where $\tilde{H}_L(\lambda, F) = (\{+, -\}, (\Lambda F, 0))$ for each active label. The right-leg equation is analogous with (26). The original mask is recorded with the injection $x \mapsto (\text{supp } x, \mathfrak{r}x)$ already proved for this chart. Neither synchronization nor the contraction identifies the three supported origins with τ .

S3.1.8 7. Global scaling defects, and their agreement with the finite extensions

Let $U_a F(x) = F(x/a)$, $a > 0$, and denote its induced continuous action on Q by $\overline{U}_a$. The section (19) gives a global continuous boundary map

$$k_a = \Lambda U_a s : Q \rightarrow V, \quad U_a s - s\overline{U}_a = \Theta k_a. \quad (29)$$

The proof applies $K + \Theta\Lambda = 1$ to $U_a s$, then uses $qU_a s = \overline{U}_a$. Therefore

$$k_{ab} = U_a k_b + k_a \overline{U}_b, \quad k_1 = 0. \quad (30)$$

The same calculation works for D and compactly supported multiplicative convolution, with $k_D = \Lambda D s$. In the explicit coordinates (20),

$$U_a|_{\mathcal{B}} = \begin{pmatrix} U_a|_V & k_a \\ 0 & \overline{U}_a \end{pmatrix}, \quad D|_{\mathcal{B}} = \begin{pmatrix} D|_V & k_D \\ 0 & D_Q \end{pmatrix}. \quad (31)$$

Thus the topological splitting is not substituted for an equivariant splitting. Equation (29) is the precise comparison between them.

For two cutoff choices, let s_0, s_1 be their sections and set $b_{10} = \Lambda_0 s_1 : Q \rightarrow V$. Then

$$s_1 - s_0 = \Theta b_{10}, \quad k_a^{(1)} = k_a^{(0)} + U_a b_{10} - b_{10} \overline{U}_a. \quad (32)$$

All dependence on the chosen representative map is carried by this displayed coboundary. No canonical cutoff or average over choices is declared.

Restrict back to PR #9 without changing its extension class Use its existing maps $s_Z : E_Z \rightarrow \mathcal{B}$, $\sigma_Z = q s_Z : E_Z \rightarrow Q$, and $J_Z : \mathcal{B} \rightarrow E_Z$. Put $b_Z = \Lambda s_Z$. The new continuous representative of the same finite arithmetic class is

$$s_Z^{\text{new}} = s \sigma_Z = K s_Z = s_Z - \Theta b_Z. \quad (33)$$

If $P(D)s_Z - s_Z M_P = \Theta k_{P,Z}$, direct substitution gives

$$k_{P,Z}^{\text{new}} = k_{P,Z} - P(D)b_Z + b_Z M_P. \quad (34)$$

For $P = h_Z$, this changes the source boundary by $-h_Z(D)b_Z$. It is zero in $V/h_Z(D)V$, so the extension class remains exactly

$$\varepsilon_Z = j_{h_Z}(h_Z/g), \quad g = 2\xi. \quad (35)$$

The polynomial residue form still becomes the arithmetic one by M_{ε_Z} ; its Jacobian contraction remains $M_{\varepsilon_Z} M_{j_h g'}$. No unit, derivative, sign, or factor of 2 is changed.

The two finite cochain projectors differ by the explicit homotopy $-b_Z J_Z$ in degree minus one. Their finite-rank trace difference is zero because $J_Z \Theta = 0$. Hence their cochain Lefschetz trace is the unchanged

$$-\sum_{\rho \in Z} m_\rho \mathcal{M}f(\rho). \quad (36)$$

S3.1.9 8. Continuous duality and completed tensor powers of the full object

Use continuous duals, denoted E'_b with the strong topology. Transpose the actual topological splitting (20). It gives

$$\boxed{0 \rightarrow Q'_b \xrightarrow{q'} \mathcal{B}'_b \xrightarrow{\Theta'} V'_b \rightarrow 0, \quad \Theta' \Lambda' = 1.} \quad (37)$$

The continuous cochain-dual complex is $[\mathcal{B}'_b \xrightarrow{\Theta'} V'_b]$ in degrees $-1, 0$. Its cohomology is Q'_b in degree -1 and zero in degree 0 . The transpose contraction proves this directly; no general exactness theorem for arbitrary locally convex quotients is assumed.

The actual finite residue map into that continuous dual is

$$\overline{E_Z} \longrightarrow Q'_b, \quad \bar{f} \longmapsto (u \mapsto R_Z(f, j_Z u)), \quad (38)$$

where $j_Z q = J_Z$. Continuity follows from the finite Mellin jets and finite dimensionality of E_Z . It is injective by their surjectivity and perfect residue duality. Multiplication by g' then gives the arithmetic finite trace pairing, with its previously calculated radical retained.

Let $\widehat{\otimes}_\pi$ denote completed projective tensor product. The comparison from the previous algebraic tensor is its canonical completion map. All chain operators in (24) are continuous. Thus their finite tensor products and homotopies extend to the completed products. With $P = sq$ on C_+ , the homotopy

$$H_n = \sum_{j=1}^n P^{\widehat{\otimes}(j-1)} \widehat{\otimes} H \widehat{\otimes} 1^{\widehat{\otimes}(n-j)} \quad (39)$$

includes $(-1)^{\sum_{i < j} |x_i|}$ on homogeneous inputs. It satisfies

$$dH_n + H_n d = 1 - P^{\widehat{\otimes} n}.$$

Consequently, for the completed external coefficient complex on the same tau-base chart product,

$$\boxed{H^k(C_+^{\widehat{\otimes} n}) = \begin{cases} Q^{\widehat{\otimes} n}, & k = n, \\ 0, & k \neq n. \end{cases}} \quad (40)$$

This follows from a split continuous contraction, not from a blanket claim that completed tensor product preserves every exact sequence.

For the joint chart use (25). Its full cohomology in degree k is the direct sum, indexed by subsets $J \subseteq \{1, \dots, n\}$ with $|J| = k$, of the ordered completed tensors having Q in the slots of J and V in the other slots. In those V slots the scaling action is $aU_{1/a}$, exactly as in the original minus-coordinate representative. The degree-zero contribution is not discarded. Split reconstruction retains each product mask and each internal zero.

S3.1.10 9. The pairing calculation is now a specified global boundary problem

The section $s : Q \rightarrow \mathcal{B} \subset L^2(dx)$ supplies a positive definite auxiliary form

$$\mathcal{H}_s(u, v) = \langle su, sv \rangle_{L^2(dx)}.$$

This is not assigned to the arithmetic Weil form. The explicit weight-covariance defect is calculated using (29) and $\langle U_a f, U_a g \rangle = a \langle f, g \rangle$:

$$\boxed{\mathcal{H}_s(\overline{U}_a u, \overline{U}_a v) - a \mathcal{H}_s(u, v) = -\langle U_a s u, \Theta k_a v \rangle - \langle \Theta k_a u, U_a s v \rangle + \langle \Theta k_a u, \Theta k_a v \rangle.} \quad (41)$$

The original source boundary and both of its cross-pairings remain. Being a boundary in Q does not assert these pairings are zero in the representative Hilbert space. In a split lift each computed zero is its supported value e .

For a reduced eigenline of the actual dilation representation with exponent ρ , the left side at $u = v$ is $(a^{2\Re\rho} - a) \mathcal{H}_s(u, u)$. Formula (41) locates that defect in the full global boundary cocycle, with the original operator retained.

A concrete comparison explaining which topology must be kept In fact ΘV is dense in $L^2(\mathbb{R}_{>0}, dx)$, although it is closed in $\mathcal{B}$. Here is a proof retaining the map between them. Set $b_* = \Theta \phi_*$ and

$$W : L^2(dx) \xrightarrow{\sim} L^2(dy), \quad W F(y) = e^{y/2} F(e^y).$$

The Fourier transform in y , with kernel $e^{-2\pi i \nu y}$, gives

$$\mathcal{F}_y W b_*(\nu) = g(1/2 - 2\pi i \nu).$$

This is nonzero almost everywhere, because g is a nonzero entire function. The span of all translates of $W b_*$ is dense in $L^2(dy)$: a vector orthogonal to all translates has Fourier transform whose product with $\overline{\mathcal{F}_y W b_*}$ is an L^1 function with zero Fourier transform, hence vanishes almost everywhere. The nonvanishing just stated then makes that vector zero. Since $W U_a b_* = a^{1/2} (W b_*)(y - \log a)$ and $U_a b_* \in \Theta V$, density follows.

The exact quotient comparison is therefore

$$\boxed{Q = \mathcal{B}/\Theta V \longrightarrow L^2(dx)/\overline{\Theta V}^{L^2} = 0.} \quad (42)$$

Its kernel is all of Q . Its split lift sends every supported input to the supported zero in $G(0) = \mathbb{B}$, while keeping external absence separate. The constructive replacement is the Frechet quotient and the explicit global section (19), not a claim that the ordinary Hilbert quotient secretly retains those classes.

S3.1.11 10. Scope of the progress toward the Deligne comparison

The selected supplied Weil II passages 3.3.4-3.3.6 put two bounds on the same compact-to-ordinary image; 6.2 retains the dualizing operation and its shifts. This continuation does not apply those bounds over a new base without their geometric proof. It makes the existing characteristic-zero arithmetic complex globally split in its precise topological category, gives its continuous dual and completed products, and computes the operator defects on those same objects.

The formerly unresolved algebraic-to-Hausdorff kernel is now zero by (16)-(21). The finite extension class and its residue/Jacobian trace are carried by (33)-(36). The full scaling boundary is (29), its dependence on the auxiliary cutoffs is (32), and its metric defect is (41). These are concrete maps available for a global comparison.

Still retained: the common kernel of all finite spectral observations, the meromorphic summand of the balanced analytic realization, and the requirement to identify the correct arithmetic polarization/weight control on the global geometric image. The density map (42) explains why discarding the stronger topology would remove the entire arithmetic cohomology, not why the supported programme should be abandoned.

The reconstruction estimate contains $1 - c_{\alpha,\beta}$; no asymptotic uniform estimate for it is proved. No global positivity, RH, GRH, or infinite trace-class theorem is claimed. No theorem from the earlier finite-range work is upgraded to a Lean certificate. The new global retraction proof itself uses only the original theta/Poisson identities, absolute Mobius inversion, the displayed Fourier compactness argument, and the two retained moment maps.

S3.1.12 11. Verification and references

The written analytic proofs are the evidence for the new analytic statements. The accompanying unittest script tests exact finite identities: divisor cancellation with supported zeros, cutoff-resolvent identities in a finite unitary model, moment corrections, contractions, synchronization masks, operator cocycles, changes of sections, preservation of extension classes, finite trace changes, and completed-tensor algebra before completion. It does not numerically certify a Fourier operator norm, an analytic convergence statement, or a Riemann zero.

Source interfaces read:

- Owner's SplitZero_Derived_Mathematics_2026-09-12(1).md, sections 1-7; the source permits nonzero bottom fibres in its general interface.
- PR #9, workbenches/tau-chain-descent/RESEARCH_NOTE.md, at the commit above; local bytes match its Git blob.
- PR #8's finite comparison as retained and invoked in #9; the sections using s_Z and J_Z are explicitly dependencies of (33)-(38), not inputs to the proof of (2).
- Supplied Weil II TeX: the actual 3.3.1-3.3.6 excerpt, including its finite-type base and duality assumptions. It was read as TeX, not obtained by OCR. No full source-proof audit is claimed.
- Ralf Meyer, *A spectral interpretation for the zeros of the Riemann zeta function*, arXiv:math/0412277: prior-context abstract only in this continuation. A source-archive retrieval failed; no unread detailed theorem is cited as a premise.

The contribution is AI-assisted under the owner's mathematical direction. Original mathematical files, formal sources, attribution and licenses are unchanged. Only authored exposition, test code and validation records are proposed for public addition; no private transcript or source-literature corpus is published.

S4 PR 11: Homotopy control

S4.1 Homotopy choices and source-preserving arithmetic control

Owner-directed SplitZero continuation, 12 September 2026. Base: PR #10, d26c283c2a58da57bb5a5a4d4bc8669019f6ebb7. This integration note records the new derivations; the conversation delivery also contains a longer equation-by-equation exposition. No original scalar definitions or formal modules are changed.

S4.1.1 1. Reviewed theorem and analytic specialization

The supplied other-session proof classifies all homotopies for

$$C = [V \oplus V \xrightarrow{d} B], \quad d(v, w) = \Theta(v - \mathcal{F}w), \quad Q = B/\Theta V,$$

where Θ is injective and $\mathcal{F}$ is an R -linear automorphism. For a fixed $\kappa: B \rightarrow V$ with $\kappa \Theta = 0$, every solution of BOTH equations

$$dH = \Theta \kappa, \quad Hd = 0$$

has the unique form

$$H_\alpha(b) = (\kappa b + \alpha q b, \mathcal{F}^{-1} \alpha q b), \quad \alpha : Q \rightarrow_R V.$$

Proof: writing $H = (u, v)$, injectivity gives $u - \mathcal{F}v = \kappa b$. Since $d(x, 0) = \Theta x$, $Hd = 0$ gives $H \Theta = 0$. Hence $\mathcal{F}v$ factors uniquely through q , and supplies α . Conversely substitution proves both equations. The reference solution is $H_0 = (\kappa, 0)$; the family is an affine space under $\text{Hom}_R(Q, V)$, relative to that reference.

Let $\gamma(v) = (v, \mathcal{F}^{-1} v)$. Then

$$H_\alpha - H_\beta = \gamma(\alpha - \beta)q.$$

The difference is a map $H_1(C) \rightarrow H_0(C)$. There are no degree-minus-two endomorphisms of this two-term coefficient complex. Thus it is a genuine degree-minus-one Hom-complex class, not an erased difference.

The supplied theorem is mathematically correct. Its Lean draft explicitly remains uncompiled, and its earlier failed chart build is not relabelled successful. No Lean or Lake executable is installed in the review environment.

For the actual analytic spaces instantiate $R = \mathbb{C}$. With the quotient topology on Q , the continuous version follows: $\alpha q = \mathcal{F} \text{pr}_2 H$ is continuous, so the quotient property makes α continuous. Conversely the displayed formula sends continuous α to continuous H .

For the polynomial action $A_0 = \mathbb{C}[t]$, Fourier has the exact type

$$\mathcal{F} : V^j \xrightarrow{\sim} V, \quad t \cdot_{V^j} v = (1 - D)v, \quad j(t) = 1 - t,$$

because $F D = (1 - D)F$. Thus d is A_0 -linear from $V + V^\wedge j$ to B . A complex-linear homotopy is not automatically A_0 -linear. The reflected module above is the actual comparison, not a change to the Fourier definition.

S4.1.2 2. Original split support on every homotopy

Retain the base b_τ and the square $G(Z) \rightarrow G(C)$ over $Z > C$. The quotient $G(Z) \rightarrow Z$ remains infinite. Both lifted coefficient maps preserve τ and the supported scalar e separately.

Use the original support lattice $L = \{\text{bottom}, +, -, J\}$, $J = \{+, -\}$. Degree-zero fibres are $0, V, V, V + V$ with the coordinate inclusions. Degree-one active fibres are all B , with identity transports. Their differentials are Θ , $-\Theta$, F and d . Retain zero modules in the other degrees; their reconstructed zero map is $z(\lambda, x) = (\lambda, 0)$.

Literal multiplication by $E_{\text{sync}} = (1, e)$ induces

$$r^0(a, b) = (a + eb, b + ea), \quad r_L(\perp) = \perp, \quad r_L(\lambda) = J(\lambda \neq \perp).$$

Every homotopy lifts by

$$\tilde{H}_\alpha(\lambda, b) = (J, (\kappa b + \alpha q b, \mathcal{F}^{-1} \alpha q b)), \quad \lambda \neq \perp; \quad \tilde{H}_\alpha(\tau) = \tau.$$

This is split-linear: two active inputs add at their joined label, both outputs add at J , and their amplitudes obey the two displayed linear formulas. A supported scalar zero gives $(J, (0, 0))$; external τ gives the global zero. Therefore

$$\tilde{d} \tilde{H}_\alpha + \tilde{H}_\alpha \tilde{d} = r \tilde{\Delta}.$$

The difference is $(J, \gamma(\alpha - \beta)qb)$, retaining its degree-zero class. For this chart, the pair $(\text{support}(x), r(x))$ is injective. No such injectivity is assumed for arbitrary diagrams with noninjective transports. For a smaller relation space W , keep $Q \rightarrow W$ with kernel $\Theta V / \Theta W$; q in the formulas means the displayed quotient by the full admitted V .

S4.1.3 3. Coherence for all dilations

Let $S_a = U_a$ on V , $T_a = U_a$ on B , $U_a F(x) = F(x/a)$, and T_{bar}_a the quotient action. The actual cochain action is

$$\tau_a^0 = (S_a, \mathcal{F}^{-1} S_a \mathcal{F}) = (U_a, a U_{1/a}), \quad \tau_a^1 = T_a.$$

It satisfies $T_a^0 \gamma = \gamma S_a$ and $q T_a = T_{\text{bar}}_a q$. With the PR #10 section s , take $P = (0, sq)$, and write

$$[\tau_a, P]^1 = \Theta \kappa_a, \quad \kappa_a = k_a q, \quad T_a s - s \bar{T}_a = \Theta k_a.$$

The commutator product identity gives $\kappa_{ab} = S_a \kappa_b + \kappa_a T_b$. The family of homotopies is composition-coherent,

$$H_{ab} = \tau_a H_b + H_a \tau_b,$$

exactly when

$$\alpha_{ab} = S_a \alpha_b + \alpha_a \bar{T}_b.$$

Proof: the reference family $(\kappa_a, 0)$ is coherent. Subtract it and use injectivity of γ and surjectivity of q . No action or boundary is omitted.

For a smoothly parameterized continuous-linear family with $L = (d/dt)|_0 \alpha(e^t)$, the exact formula is

$$\alpha_{e^t} = \int_0^t S_{e^{t-r}} L \bar{T}_{e^r} dr.$$

This is a vectorwise integral in the complete Frechet source, with the original oriented integral for negative t . Differentiating the composition equation gives the formula; splitting the integral proves its converse. In particular $\alpha_a = S_a b - b \bar{T}_a$ has infinitesimal parameter $D_V b - b D_Q$.

S4.1.4 4. A homotopy parameter leaves the control form fixed

Fix an actual finite arithmetic packet with full multiplicities,

$$h_Z(t) = \prod_{\rho \in Z} (t - \rho)^{m_\rho}, \quad E_Z = \mathbb{C}[t]/(h_Z), \quad A = M_t.$$

Use the existing $R: E_Z \rightarrow B$ and $J_Z: B \rightarrow E_Z$ with

$$qR = \sigma_Z, \quad J_Z R = 1, \quad J_Z \Theta = 0, \quad J_Z D = A J_Z, \quad DR - RA = \Theta k.$$

The cochain projector $P_R = (0, R|_Z)$ has commutator $(0, \Theta k|_Z)$, so the reviewed theorem applies with $\kappa = k|_Z$. The quotient $\text{jet } J_{\text{bar}}_Z$ satisfies $J_{\text{bar}}_Z \sigma_Z = 1$, hence any $\alpha_E: E_Z \rightarrow V$ extends to $\alpha_E J_{\text{bar}}_Z$ on Q . Restriction to R gives

$$H_{\alpha_E} R = (k + \alpha_E, \mathcal{F}^{-1} \alpha_E), \quad dH_{\alpha_E} R = \Theta k.$$

Take $H = L^2(R_+, dx)$ with the original inner product, conjugate-linear in the first variable. Define

$$G_R = R^* R, \quad B_R = \Theta k, \quad W_R = -(R^* B_R + B_R^* R).$$

The composite of actual maps

$$\text{Hom}_{\mathbb{C}}(E_Z, V) \longrightarrow \text{Hom}(E_Z, V^2) \xrightarrow{d \circ (-)} \text{Hom}(E_Z, H) \xrightarrow{B \mapsto -(R^* B + B^* R)} \text{Herm}(E_Z)$$

is constant at W_R . Its last map is real-linear. The retained H^0 ambiguity does not change this boundary contraction.

Integration by parts on the actual source functions gives

$$A^* G_R + G_R A - G_R = W_R.$$

The boundary term $[x \text{ conjugate}(F)H]_0^\infty$ vanishes by the stated decay. No claim that a θ boundary is orthogonal to a representative is used.

S4.1.5 5. The actual representative-change family

Every representative of the same inclusion σ_Z is uniquely

$$R_b = R + \Theta b, \quad b : E_Z \rightarrow_{\mathbb{C}} V.$$

Indeed $q(R'-R)=0$ gives values in ΘV , and the PR #10 retraction gives the unique $b=\Lambda(R'-R)$. Finite source dimension gives continuity. Global continuous sections have the identical formula with $b:Q \rightarrow V$ continuous.

The complete changes are

$$k_b = k + D_V b - bA,$$

$$\delta G_b = R^* \Theta b + (\Theta b)^* R + (\Theta b)^* \Theta b,$$

$$\boxed{W_{R_b} - W_R = A^* \delta G_b + \delta G_b A - \delta G_b.}$$

Their extension-coordinate map is $U_b(v,u)=(v+bu,u)$, and

$$U_b^{-1} \begin{pmatrix} D_V & k \\ 0 & A \end{pmatrix} U_b = \begin{pmatrix} D_V & k + D_V b - bA \\ 0 & A \end{pmatrix}.$$

Lift that automorphism on the common active fibre $(V+E_Z)^{\tau}$. For the original masks, first keep the pair $(\text{support}(x), r(x))$; apply the shear on the joint fibre, and recover the original amplitudes by U_b^{-1} and the original mask by its recorded component. No inverse to the unrecorded support collapse is asserted.

The projectors obey $P_{(R_b)} - P_R = \text{partial } L_b$ with $L_b^{-1}(F)=(b|_Z F, 0)$. Their finite cochain traces agree because

$$\text{Tr}(\Theta b J_Z H_f) = \text{Tr}(J_Z H_f \Theta b) = 0.$$

The cochain supertrace sign remains -1 in degree one. The arithmetic extension class changes by $h_Z(D)b(1)$, so its class in $V/h_Z(D)V$ remains $\epsilon_Z = j_h(h_Z/(2\pi))$. The residue/Jacobian trace form is consequently unchanged.

S4.1.6 6. Finite actual source ansatz and one master Gram matrix

Retain $\phi = (4\pi^2 x^4 - 6\pi x^2) \exp(-\pi x^2)$, $\phi_j = D^j \phi$, and

$$\Phi_m : \mathbb{C}^{m+1} \rightarrow V, \quad (c_j) \mapsto \sum_{j=0}^m c_j \phi_j.$$

Their actual Mellin identities are $M \Theta \phi_j(s) = 2\pi i(s)^j$. They remain in the original two-moment source and are linearly independent. The source section $R_0 = s_Z$ has the exact rank-one defect $DR_0 - R_0 A = \Theta \phi^* \ell_Z$, with the unchanged arithmetic remainder functional ℓ_Z .

Define maps, including the target enlargement,

$$I_m e_j = e_j, \quad S_m e_j = e_{j+1}, \quad I_m, S_m : \mathbb{C}^{m+1} \rightarrow \mathbb{C}^{m+2}, \quad D\Phi_m = \Phi_{m+1} S_m.$$

For B in $\text{Mat}_{((m+1) \times d)}(\mathbb{C})$, $d = \dim E_Z$, put

$$R_B = R_0 + \Theta \Phi_m B, \quad K_B = e_0 \ell_Z + S_m B - I_m B A.$$

Then

$$DR_B - R_B A = \Theta \Phi_{m+1} K_B, \quad q R_B = \sigma_Z, \quad J_Z R_B = 1.$$

Take the actual column map and its Gram matrix

$$\mathcal{T}_m : E_Z \oplus \mathbb{C}^{m+2} \rightarrow L^2(\mathbb{R}_+, dx), \quad (u, c) \mapsto R_0 u + \Theta \Phi_{m+1} c, \quad M_m = \mathcal{T}_m^* \mathcal{T}_m.$$

M_m is positive definite. Applying J_Z to a vanishing combination gives $u=0$; Mellin then gives $c=0$. Its entries are the convergent integrals of the displayed arithmetic functions, with the original measure.

Define

$$X_B = \begin{pmatrix} I_d \\ I_m B \end{pmatrix}, \quad Y_B = \begin{pmatrix} 0 \\ K_B \end{pmatrix}.$$

The complete control calculation is

$$\boxed{G_B = X_B^* M_m X_B, \quad W_B = -(X_B^* M_m Y_B + Y_B^* M_m X_B) = A^* G_B + G_B A - G_B.}$$

This restricts representative choice to an actual finite family of theta boundaries. It is not an arbitrary positive matrix ansatz, and it is not asserted to exhaust all continuous source corrections. All packet coordinates, multiplicities, local units and finite source-degree changes are retained.

S4.1.7 7. Error transport, duality, and the remaining estimate

With actual enclosures $||M - \hat{M}|| \leq \eta_M$, $||X - \hat{X}|| \leq \eta_X$, $||Y - \hat{Y}|| \leq \eta_Y$, put $x = ||\hat{X}||$, $y = ||\hat{Y}||$, $m_0 = ||\hat{M}||$. Product estimates give

$$\eta_G = \eta_M (x + \eta_X)^2 + m_0 (2x\eta_X + \eta_X^2),$$

$$\eta_W = 2[\eta_M (x + \eta_X)(y + \eta_Y) + m_0 (x\eta_Y + y\eta_X + \eta_X \eta_Y)].$$

These include coefficient errors, not just quadrature errors. Exact certificates for $\hat{G} - \eta_G I > 0$ and

$$\epsilon \hat{G} \pm \hat{W} - (\epsilon \eta_G + \eta_W) I \succeq 0$$

imply the actual two-sided control. This is an error-transfer theorem; arithmetic enclosures have not been computed here.

The unchanged residue matrix S satisfies $S^* = -S$ and $A^* S + S A = S$. Its exact dual transport is

$$G_B^D = S^* G_B^{-1} S, \quad W_B^D = -S^* G_B^{-1} W_B G_B^{-1} S.$$

Thus an upper certificate gives a lower certificate on the same arithmetic packet. The Weil form stays $S J_g$, with metric comparison $G_B^{-1} S J_g$; no positivity is assigned by choosing G_B .

For tensor degree n , retain $A_n = \sum_j 1$ tensor A tensor 1 and $G_{(B,n)} = G_B^{\wedge}(\text{tensor } n)$. The product control is $\sum_j G_B$ tensor W_B tensor G_B . Changing a homotopy by $\gamma \alpha q$ changes

the tensor homotopy by its Koszul-signed insertions; its differential is zero, hence it does not change that control form.

The existing orbit construction on this actual tensor image gives

$$G_{B,n,T} = \int_0^T e^{-nt} e^{tA_n^*} G_{B,n} e^{tA_n} dt,$$

$$A_n^* G_{B,n,T} + G_{B,n,T} A_n - n G_{B,n,T} = e^{-nT} e^{TA_n^*} G_{B,n} e^{TA_n} - G_{B,n}.$$

Every occurrence of $G_{B,n}$ now has the explicitly constrained source in section 6.

A nonzero boundary need not have nonzero control. The exact calibration $D_{\text{amb}} = \text{diag}(1/2+i, 1/2+2i)$, $\Theta(v) = (v, 0)$, $A = 1/2+2i$, $R(u) = (u, u)$ has boundary $\Theta(-i)$, Gram 2, and control zero. It is an algebraic calibration, not a zeta packet. The real-linear map $B \mapsto (R^*B + B^*R)$ explains which nonzero boundaries can have zero control.

Conversely every eigenvector $Av = \rho v$ obeys

$$\frac{v^* W_B v}{v^* G_B v} = 2\Re \rho - 1.$$

This ensures that changing representatives has not changed a spectral coordinate. The analytic target is now to bound the actual matrices from section 6, or their tensor-orbit endpoints, with all packet and tensor dependence retained. No uniform purity estimate, RH, GRH, or global spectral-kernel vanishing is proved here.

S4.1.8 8. Validation and attribution

The attachment supplies the homotopy-classification theorem and the uncompiled draft. This note verifies its proof and adds the continuous/twisted interface, supported reconstruction, coherent-family condition, and the connection to the actual control matrices. The original owner-directed SplitZero construction remains the source.

The independent checker has sixteen exact unittest methods, including finite parameter families. They passed normally and under python -O with identical successful JSON records. Intentional negative controls failed in both modes. The previous control checker also passed its sixteen methods. These finite checks cover algebraic models and polynomial-times-exponential integral calibrations, not evaluated zeta packets or analytic/Lean certification.

General references: The Stacks Project, Tags 0A8H and 0115 for the Hom-complex differential and homotopy, and 010I and 06XP for extension classes. The formulas above are proved on the specified programme objects; those references are not imported as a number-field weight theorem. Only authored notes, test code and validation records are published; no private transcript, source-literature corpus, or font files are included.

S5 PR 13: Orthogonal boundary control

S5.1 Orthogonal theta boundaries and rank-two arithmetic control

Owner-directed SplitZero continuation, 12 September 2026. Base: PR #11, d37eade4f9e6a82c1a88aeff710a3b851a34eb49. This is an additive research contribution with written proofs for review, not a new Lean certificate for the analytic results. The conversation delivery contains a longer numbered LaTeX/HTML version, the full reading record, and exploratory arithmetic moments.

S5.1.1 1. Reviewed input and exact types

The supplied other-session theorem is correct: for injective $\Theta: V \rightarrow B$, an R -linear automorphism F , $Q = B/\Theta V$, and $\kappa: B \rightarrow V$ with $\kappa \Theta = 0$, all homotopies satisfying BOTH $dH = \Theta \kappa$ and $Hd = 0$, for $d(v, w) = \Theta(v - Fw)$, are

$$H_\alpha(b) = (\kappa b + \alpha \kappa b, F^{-1} \alpha \kappa b), \quad \alpha: Q \rightarrow R V.$$

Writing $H = (u, v)$ gives $u - Fv = \kappa$. Since $d(x, 0) = \Theta x$, $Hd = 0$ gives $H \Theta = 0$; hence Fv descends uniquely to α . Substitution proves the converse. The difference is $\gamma(\alpha - \beta)q$ with $\gamma(v) = (v, F^{-1}v)$. The solution set is affine relative to H_0 , not generally a vector space with the zero homotopy as origin.

The attachment's uncompiled-draft status has now been superseded by the other session's successful PR #12 at 5d2772ea0a16d177ac3e01ff70394b90ba95a232. The actual SplitZeroTauHomotopy.lean, completed job 103535438942, and its full log were read. Both cochain equations and the inverse equivalence passed the specified kernel checks. Retraction and quotient-topology interfaces also passed with their explicit hypotheses. This is the other session's formalization; neither the actual analytic theta construction nor the new Gram/control results below are certified by it. No local Lean/Lake execution is claimed. See COORDINATION_UPDATE.md for exact scope. PR #11 already supplies the continuous specialization, the Fourier twist over $C[t]$, support-changing lifts, coherent dilations and representative-change formulas. Those are retained inputs, not new results here.

Keep the original tau base and the square $G(Z) \rightarrow G(C)$ over $Z \rightarrow C$, with $p: G(Z) \rightarrow Z$ still infinite, $e = \text{ofR}(0)$, and tau the external scalar zero. No Boolean localization replaces the base quotient. All quotient relations below use the original internal coequalizer and preserve the support label.

Retain V, B and the actual operators of PRs #8-#11:

```
V={even Schwartz phi on R: phi(0)=0 and integral(phi)=0};
B={smooth F on R_+: sup x^b |D^k F(x)| < infinity for all integer b and k>=0};
D=-x d/dx; Theta phi(x)=2 sum_(n>=1) phi(nx);
M F(s)=integral_0^infinity F(x)x^s dx/x;
phi_*= (4 pi^2 x^4 - 6 pi x^2) exp(-pi x^2);
phi_j=D^j phi_*; f_j=Theta phi_j=D^j f_0;
M f_j(s)=s^j g(s), g=2 xi.
```

The Hilbert observation is $H=L^2(\mathbb{R}_+, dx)$, conjugate-linear in the first argument. Polynomial packet coordinates are retained, not changed to orthonormal coordinates.

For an actual finite packet with all multiplicities, let $E=C[t]/h_Z$, $A=M_t$. The previous analytic constructions supply

$$R_\theta: E \rightarrow B, \quad J_Z: B \rightarrow E, \quad qR_\theta = \sigma_Z, \quad J_{ZR_\theta} = 1, \quad J_Z \theta = 0, \\ DR_\theta - R_\theta A = f_\theta \text{ ell}_Z.$$

The exact ell_Z comes from $\epsilonpsilon_Z = j_h(h/(2\xi))$; at a simple zero its value on 1 is $1/(2\xi'(\rho))$. These analytic constructions remain the cited research-proof dependencies, not theorems certified by the finite tests here.

S5.1.2 2. An actual minimum over the admitted theta relations

For $m \geq 0$ define

$$W_m = \text{span}(\phi_0, \dots, \phi_m); \\ \phi_m: C^{(m+1)} \rightarrow V, \quad c \mapsto \sum c_j \phi_j; \\ F_m = \theta \phi_m: C^{(m+1)} \rightarrow H; \\ H_m = F_m^* F_m; \quad C_m = F_m^* R_\theta; \quad G_\theta = R_\theta^* R_\theta.$$

The ϕ_j are independent: Mellin sends a relation to $g(s)P(s)=0$. Thus H_m is positive definite. Here C_m is a cross-Gram matrix $E \rightarrow C^{(m+1)}$, not the complex of that name in the endpoint workbench.

Set

$$B_m = -H_m^{-1} C_m; \\ \pi_m = F_m H_m^{-1} F_m^*; \\ R_m = R_\theta + \theta \phi_m B_m = (1 - \pi_m) R_\theta.$$

The correction is a finite original theta boundary, so R_m lands in B , $qR_m = \sigma_Z$, and $J_{ZR_m} = 1$ at every m . Direct multiplication proves

$$F_m^* R_m = 0; \\ G_m = R_m^* R_m = G_\theta - C_m^* H_m^{-1} C_m > 0.$$

Positive definiteness follows from $J_{ZR_m} = 1$. For any $B: E \rightarrow C^{(m+1)}$,

$$(R_\theta + F_m B)^* (R_\theta + F_m B) \\ = G_\theta + (B - B_m)^* H_m (B - B_m).$$

This is the minimum of the Hilbert Gram within the stated source family, not yet a minimum of its relative weight error. Also $(1 - \pi_m)(R_\theta + F_m B') = R_m$: changing the initial representative by a relation already in W_m leaves the result unchanged.

S5.1.3 3. The complete control form has rank at most two

Let $I_m, S_m: C^{(m+1)} \rightarrow C^{(m+2)}$ be $I_m e_j = e_j$ and $S_m e_j = e_{(j+1)}$. Define

$$K_m = e_\theta \text{ ell}_Z + S_m B_m - I_m B_m A.$$

Then

$$DR_m - R_m A = F_{(m+1)} K_m = \theta (\phi_{(m+1)} K_m).$$

No boundary component is discarded in this identity. Put $b_m = e_m^* B_m: E \rightarrow C$, and $z_m = R_m^* f_{(m+1)}: C \rightarrow E$. Integration by parts on the stated source functions gives

$$\langle DF, H \rangle + \langle F, DH \rangle = \langle F, H \rangle,$$

with vanishing boundary term $[x \text{ conjugate}(F)H]_0^\infty$. Hence

$$\begin{aligned} W_m &= A^* G_m + G_m A - G_m \\ &= -(R_m^* F_{(m+1)} K_m + K_m^* F_{(m+1)}^* R_m) \\ &= -z_m b_m - b_m^* z_m^*. \end{aligned}$$

The last equality uses $F_m^* R_m = 0$ and the exact last row of K_m , which is b_m . Thus $\text{rank}(W_m) \leq 2$ for every packet dimension and every finite m . The pairings with the first $m+1$ theta directions vanish; those supported vectors themselves are retained.

Define the actual scalar quantities

$$\begin{aligned} u_m &= z_m^* G_m^{-1} z_m \geq 0; \\ v_m &= b_m^* G_m^{-1} b_m \geq 0; \\ c_m &= b_m^* G_m^{-1} z_m. \end{aligned}$$

The nonzero spectrum of $G_m^{-1} W_m$ is the nonzero spectrum of

$$-\begin{bmatrix} c_m & v_m \\ u_m & \text{conjugate}(c_m) \end{bmatrix}.$$

This follows by factoring through the two-column map $[z_m, b_m^*]$ and using the equality of nonzero spectra of the two compositions. Its trace is $-2 \text{Re}(c_m)$, determinant $|c_m|^2 - u_m v_m$. Therefore the least symmetric control allowance is

$$\begin{aligned} \epsilon_m &= |\text{Re}(c_m)| + \sqrt{u_m v_m - (\text{Im}(c_m))^2}, \\ -\epsilon_m G_m &\leq W_m \leq \epsilon_m G_m. \end{aligned}$$

Cauchy-Schwarz makes the radicand nonnegative. The formula also covers rank one. A reflection-stable full packet has

$$\text{trace}(G_m^{-1} W_m) = 2 \text{Re}(\text{trace } A) - \dim E = 0,$$

so $\text{Re}(c_m) = 0$. This is an exact trace identity, not a choice of coordinates. For every eigenvector $Av = \rho v$,

$$(v^* W_m v) / (v^* G_m v) = 2 \text{Re}(\rho) - 1.$$

Thus the relative control still detects precisely the original spectral weight.

S5.1.4 4. The next relation is a rank-one update with its own retained coordinate

Set

$$\begin{aligned} a_{(m+1)} &= (1 - \Pi_m) f_{(m+1)} = \Theta \psi_{(m+1)}, \\ \psi_{(m+1)} &= \phi_{(m+1)} - \Pi_m H_m^{-1} F_m^* f_{(m+1)}, \\ \eta_{(m+1)} &= \|a_{(m+1)}\|^2 > 0. \end{aligned}$$

Then $R_m^* a_{(m+1)} = z_m$, and orthogonal decomposition gives

$$\begin{aligned} \Pi_{(m+1)} &= \Pi_m + a_{(m+1)} \eta_{(m+1)}^{-1} a_{(m+1)}^*; \\ R_{(m+1)} &= R_m - a_{(m+1)} \eta_{(m+1)}^{-1} z_m^*; \\ G_{(m+1)} &= G_m - \eta_{(m+1)}^{-1} z_m z_m^*. \end{aligned}$$

The control update is obtained by applying the same real-linear operator $X \mapsto A^*X + XA - X$ to the last identity.

The original quotient transport is

$$Q_W = B / \Theta_{W_m} \rightarrow Q_{W(m+1)} = B / \Theta_{W(m+1)},$$

$$\text{kernel} = \Theta_{W(m+1)} / \Theta_{W_m} \simeq W(m+1) / W_m.$$

That kernel is one-dimensional. The square $E \rightarrow Q_W$ by R_m and $E \rightarrow Q_{W(m+1)}$ by $R(m+1)$ commutes. The new relation becomes the supported zero only through the actual next-level quotient; it is not another scalar adjunction at the bottom.

There is a form on the entire quotient:

$$\text{Hcal}_m([F], [G]) = \langle (1 - \Pi_m)F, (1 - \Pi_m)G \rangle.$$

It is positive definite since the kernel of $1 - \Pi_m$ in B is exactly Θ_{W_m} . Let $\lambda_{m+1}[F] = \langle a_{m+1}, F \rangle$. This is well defined on Q_W and

$$\text{Hcal}_m(x, y) = \text{Hcal}_{m+1}(qx, qy) + \eta_{m+1}^{-1} \text{conjugate}(\lambda_{m+1}(x)) \lambda_{m+1}(y).$$

The map $(q, \lambda_{m+1}): Q_W \rightarrow Q_{W(m+1)}$ plus C is a linear isomorphism. Its inverse is

$$([F], c) \mapsto [F - a \eta_{m+1}^{-1} \langle a, F \rangle + a \eta_{m+1}^{-1} c]_{W_m}.$$

Changing F by a relation at level $m+1$ changes this expression only by a relation at level m . This supplies the exact metric comparison between levels instead of treating the quotient transports as isometries.

Every displayed linear map has its original fixed-support lift. On the full source chain, reconstructed addition uses the join $\max(m, n)$ and the above transports. The scalar e sends $(m, [F])$ to $(m, [0])$; τ sends it to external absence. The two-leg primitives are $(k_m u, 0)$ and $(0, \text{Fourier}^{-1} k_m u)$, where $k_m = \Phi_{m+1} K_m$. Synchronization by the original $E_{\text{sync}} = (1, e)$ supplies their common joint support. Their difference remains the H_0 cycle $(k_m u, \text{Fourier}^{-1} k_m u)$. The other session's $\text{Hom}(Q, H_0)$ freedom leaves their differential and hence W_m unchanged.

S5.1.5 5. Actual arithmetic moments and their truncation allowance

The matrices H_m come from the original arithmetic functions. Since $JF(x) = x^{-1} F(1/x)$ is unitary on $L_2(dx)$, $Jf_0 = f_0$ and $JD = (1 - D)J$,

$$H_{ij} = \int_0^1 \text{conjugate}(f_i) f_j + \text{conjugate}(f_i^{\text{ref}}) f_j^{\text{ref}} dx,$$

$$f_j^{\text{ref}} = (1 - D)^j f_0.$$

This retains both multiplicative ends and permits absolutely convergent Gaussian sums on $x \geq 1$. Write

$$\phi_j(x) = P_j(x) \exp(-\pi x^2),$$

$$P_0 = 4 \pi^2 x^4 - 6 \pi x^2,$$

$$P_{j+1} = 2 \pi x^2 P_j - x P_j',$$

$$P_j = \sum_r c_{j,r} x^{2r},$$

$$c_{j+1,r} = 2 \pi c_{j,r-1} - 2r c_{j,r}.$$

For $f_j^{[N]}(x) = 2 \sum_{n=1}^N P_j(nx) \exp(-\pi n^2 x^2)$, put

$$C_j = \sum_r |c(j, r)| \sqrt{\Gamma(2r+1/2) / (2 \pi^{(2r+1/2)})}.$$

Then

$$\begin{aligned} & \|f_j - f_j^N\|_{L^2([1, \infty))} \\ & \leq 2 C_j (N+1)^{-1/2} \exp(-\pi(N+1)^2/2) \\ & \quad / [1 - \exp(-\pi(2N+3)/2)]. \end{aligned}$$

Proof: on $x \geq 1$, $2 \pi n^2 x^2 \geq \pi n^2 + \pi n^2 x^2$. Integrating each monomial's squared bound gives $n^{-1/2} \exp(-\pi n^2/2)$ times the displayed gamma constant. Minkowski and a geometric bound on consecutive n terms give the formula. The reflected derivative retains the absolute binomial sum of these allowances.

The finite integral entries use exactly

$$\begin{aligned} & \text{integral}_1^{\infty} x^{(2k)} \exp(-c x^2) dx \\ & = \Gamma(k+1/2, c) / (2 c^{(k+1/2)}), \quad c = \pi(n^2 + n'^2). \end{aligned}$$

For truncation tail norms δ_i, δ_j , each inner-product error is bounded by $\delta_i \|f_j^N\| + \|f_i^N\| \delta_j + \delta_i \delta_j$, plus its reflected contribution. Numerical evaluation errors for the finite expression still require their own enclosure. The optional conversation computation is explicitly exploratory, not interval-certified.

The exact consistency check is $H_{(i+1, j)} + H_{(i, j+1)} = H_{ij}$. Cross-Gram columns $F_m \cdot R_0$ remain their actual source integrals and are not replaced by arbitrary matrices.

S5.1.6 6. The same source proves a strong topology comparison

For this actual f_0 ,

$$\text{closure span}\{D^j f_0 : j \geq 0\} \text{ in } L^2(\mathbb{R}_+, dx) = H.$$

Proof. The explicit unitary Mellin-line map sends F to $M F(1/2+it)$ in $L^2(\mathbb{R}, dt/(2\pi))$. It sends D to $1/2+it$ and f_j to $(1/2+it)^j g(1/2+it)$. The log-space function $h(z) = \exp(z/2) f_0(\exp z)$ is holomorphic in $|\text{Im } z| < \pi/4$ by its Gaussian series. For $|\text{Im } z| \leq a < \pi/4$ it decays superexponentially as $\text{Re } z$ tends to positive infinity. Poisson gives $h(z) = h(-z)$, so the same holds at the other end. Fourier contour displacement therefore gives $|g(1/2+it)| \leq C_a \exp(-a|t|)$.

The measure $d\mu = |g(1/2+it)|^2 dt/(2\pi)$ has a positive exponential moment. If an $L^2(\mu)$ function is orthogonal to all polynomials, multiplying μ by its conjugate gives a finite complex measure with a smaller positive exponential moment. Its Fourier transform is analytic in a strip and all derivatives at zero vanish. Analyticity and uniqueness of the Fourier transform imply that measure is zero. Thus polynomials are dense in $L^2(\mu)$. Multiplication by g is unitary from this weighted space onto $L^2(dt/(2\pi))$, because the nonzero analytic function g on the line is nonzero almost everywhere. This proves the assertion without RH.

As a result, for a fixed finite packet,

$$\begin{aligned} & R_m \rightarrow 0 \text{ in } \text{Hom}(E, H), \quad G_m \rightarrow 0 \text{ and } W_m \rightarrow 0, \\ & \text{while } q_{R_m} = \sigma_Z \text{ and } J_{ZR_m} = 1 \text{ for every } m. \end{aligned}$$

This specifies why unscaled smallness of W_m cannot be used alone as weight control: its denominator G_m is also shrinking. The exact relative formula in section 3 must be retained.

The corrective map is the Hilbert/jet graph:

$$\begin{aligned} & \text{closure}\{(F, J_{ZF}) : F \text{ in } B\} = H \text{ plus } E; \\ & \text{closure}\{(\Theta \phi, 0) : \phi \text{ in } V\} = H \text{ plus } 0. \end{aligned}$$

Indeed finite theta polynomials give every $(h,0)$ in the closure, and the sequence $(R_m u, u)$ gives $(0, u)$. For a specified positive metric on E , completion in $\|F\|_2^2 + \|J_Z F\|_E^2$ is this graph closure, and the quotient by the boundary closure is E by $[(h, u)] \rightarrow u$. The added metric is retained supplied data, not an implied positivity theorem for the Weil pairing.

Its split observation is

$$((R_m u)^{\bullet}, u^{\bullet}) \rightarrow (e_H, u^{\bullet})$$

in the product of the stated support-fibre topologies. The arithmetic component survives above a supported Hilbert zero. External absence is (τ, τ) .

S5.1.7 7. Duality, trace and scope

The original residue map has matrix S with $S^* = -S$ and $A^*S + SA = S$. Its pullback of the dual metric is

$$\begin{aligned} G_m^* D &= S^* G_m^{-1} S, \\ W_m^* D &= -S^* G_m^{-1} W_m G_m^{-1} S. \end{aligned}$$

Thus the upper-to-lower comparison is retained on the same arithmetic packet. The Weil pairing stays $S J_g$, with explicit metric comparison $G_m^{-1} S J_g$. Its positivity is not imposed by choosing a positive Gram matrix.

All representative changes above are original theta boundaries. Their extension class $j_h(h/(2\xi))$ is unchanged; the induced finite cochain projectors differ by the homotopy $(b)_Z, 0$. The trace difference is zero because $J_Z \Theta = 0$. Degree-one and tensor Koszul signs remain those of the source complex. On a raw tensor metric, the inserted W_m terms give the copied allowance $n \epsilon_m$; tensoring alone does not improve it.

The new results are the actual orthogonal source choice, rank-two boundary formula, exact relative certificate, rank-one source-kernel recurrence, arithmetic moment tail bound, and the full Hilbert/jet topology comparison. No uniform arithmetic purity estimate, global spectral-kernel vanishing, RH or GRH is asserted.

The thirteen finite exact tests check the encoded algebra and declared calibration models, not infinite analytic arguments or actual zeta zeros. The complete cochain-homotopy theorem remains the other session's result, now supported by the independently inspected successful PR #12 run. Its certificate does not extend to the new analytic control results. Existing Lean modules and earlier validation receipts are untouched.

References: live PR #11 at the pinned head; successful PR #12 and source/job references in COORDINATION_UPDATE.md; the supplied `Tau_Deligne_Control` and `Tau_Global_Comparison` source notes; the supplied other-session homotopy proof; the previously retained Weil II 3.3.4-3.3.6 and 6.2 duality excerpts. Standard orthogonal-polynomial context is NIST DLMF 18.2; the density argument needed here is proved above for the actual arithmetic measure.

S6 PR 17: Spectral-sum descent and the complete relative arithmetic fibre

S6.1 Spectral-sum descent with the relative arithmetic fibre retained

Owner-directed continuation, 12 September 2026. Draft for review; no purity or RH theorem is claimed. Base: PR #14 at 3bff1b2bd87dfa2592f65c5ccc231f6ee9541dfc.

S6.1.1 1. Original source and scope

Keep $G(R) = \{\tau\} \text{ disjoint-union } \{r^\bullet\}$, $e_R = 0_R^\bullet$, and the original square $G(Z) \rightarrow G(C)$ over $Z \rightarrow C$. The first arithmetic quotient remains infinite. Fixed-label linear maps lift by $(\lambda, v) \rightarrow (\lambda, Tv)$ and fix external absence; a vanishing value remains the original labelled supported zero.

Use the existing $C_+ = [V \rightarrow \Theta_B]$, $Q = B/\Theta \setminus V$, $D = -x/d/dx$, $g = 2/x$, and the actual source function $\phi_* = (4\pi^2 x^4 - 6\pi x^2)\exp(-\pi x^2)$. For a finite packet h of actual zeros, including full orders, the prior analytic construction supplies F_h with Mellin transform g/h . Retain

$$T_h(P) = P(D)F_h, \quad T_h(hP) = \Theta(P(D)\phi_*), \quad J_h T_h(P) = v_h[P]_h,$$

where $\text{upsilon}_h = j_h(g/h)$ is the full invertible jet, not the scalar e . These analytic range statements are inputs from the previous work, not newly Lean-certified here.

For k factors, the actual numerator is $P_M = C[s_1, \dots, s_k]_{(\text{degree} \leq M)}$, the relation space is its intersection with $(h(s_1), \dots, h(s_k))$, and its theta realization is $B_-(k, M)$. The canonical representative $R_-(k, M)$ is the unique least-norm lift with exactly these relations allowed. Its full jets, arithmetic class, Gram G and control W remain those of #14.

The supplied Kernel Layer Integration supplement agrees with the Symmetric Frontier note under $K = C_{\text{inverse}}$, $U = F$, $D = \Omega$, $E_{\text{layer}} = b_M$, and $F_{\text{derivative}} = \Omega^{(-1)}E_{\text{plus}}$. Its sharper rank and original-layer identities are retained as source results, not counted again as new work.

S6.1.2 2. An actual one-parameter pushforward and its resolution

Define

$$\iota_k : \mathbb{C}[S] \rightarrow E_h^{\otimes k}, \quad S \mapsto [s_1 + \dots + s_k].$$

Restriction of modules through this map is the exact quasi-coherent pushforward along the finite scheme morphism. Its adjunction maps are $f \rightarrow (1 \rightarrow f(1 \otimes 1))$ and $a \otimes 1 \rightarrow a f(1)$. Applying G gives $p \setminus G(\iota) = \iota \setminus p$, with e sent to e and τ to τ ; the morphism is over the same absolute pointed base. No finite field is substituted.

For the actual finite image E , with sum operator A , there is the free resolution

$$0 \rightarrow \mathbb{C}[S] \otimes E \xrightarrow{SI-A} \mathbb{C}[S] \otimes E \xrightarrow{\text{ev}_A} E_A \rightarrow 0.$$

Its augmentation sends $P \backslash \text{tensor} \backslash v$ to $P(A)v$. Injectivity follows from the highest polynomial coefficient. Exactness follows from

$$S^j v - A^j v = (SI - A) \sum_{i=0}^{j-1} S^{j-1-i} A^i v.$$

Dualizing with $\mathbb{C}[S] dS$ gives $SI - A^{\vee}$ in degrees 0,1, where $A^{\vee}(\lambda) = \lambda$ compose A is the algebraic transpose, not a Hermitian adjoint. Thus

$$\text{Ext}_{\mathbb{C}[S]}^1(E_A, \mathbb{C}[S]dS) \cong E^{\vee},$$

with $[\sum S^j \lambda_j dS] \rightarrow \sum (A^{\vee})^j \lambda_j$ and inverse the constant class. With $\mathbb{C}[b]^i = \mathbb{C}^{i+b}$, the exact shifted statement is

$$R\text{Hom}(E_A[-k], \mathbb{C}[S]dS[1]) \simeq E^{\vee}[k].$$

The right adjoint is the specified module functor $R\text{Hom}_{\mathbb{C}[S]}(E_h^{\text{tensor } k}, -)$. This is not an assertion about pushforward on all sheaves of modules. See Stacks Tags 0AVV and 0AWZ.

The same duality has the concrete pairing

$$\langle v, [P(S)dS] \rangle = \sum_{\lambda \in \text{Spec } A} \text{Res}_{S=\lambda} P(S)((SI - A)^{-1}v)dS.$$

Expansion at infinity gives $\sum \lambda_j (A^j v)$, proving the formula and perfectness. On a length- l block,

$$(SI - A)^{-1} = \sum_{j=0}^{l-1} \frac{N^j}{(S - \lambda)^{j+1}}.$$

All poles are retained before taking the trace. The further observation is

$$\text{Tr}(\psi(A)) = \sum_{\lambda} \text{Res}_{S=\lambda} \psi(S) \frac{\chi'_A(S)}{\chi_A(S)} dS.$$

Here $\chi_A = \det(SI - A)$ is the finite characteristic polynomial, not a replacement for $g=2x$. With $\psi(S) = a^S$ this is the finite trace of the same diagonal scaling correspondence; its cochain sign is $(-1)^k$.

S6.1.3 3. Exact symmetric-square relation algebra

Retain the coordinate morphisms

$$S = s_1 + s_2, \quad r = s_1 - s_2, \quad \Delta = r^2, \quad s_1 = (S + r)/2, \quad s_2 = (S - r)/2.$$

Swap fixes S and negates r . Even/odd polynomial expansion gives the filtered algebra isomorphism $\Phi: \mathbb{C}[S, \Delta] \rightarrow \mathbb{C}[s_1, s_2]^{\text{swap}}$, with $\deg(S)=1$, $\deg(\Delta)=2$.

Define H_0, H_1 without localizing away from $r=0$:

$$h((S+r)/2) = H_0(S, r^2) + rH_1(S, r^2), \quad h((S-r)/2) = H_0(S, r^2) - rH_1(S, r^2).$$

Then

$$(E_h \otimes E_h)^{S_2} \cong \mathbb{C}[S, \Delta]/(H_0, \Delta H_1).$$

Proof: the original ideal in $\mathbb{C}[S, r]$ is (H_0, rH_1) . Averaging an expression $H_0 \setminus a + r \setminus H_1 \setminus b$ under $r \rightarrow -r$ gives exactly $H_0 \setminus a_{\text{even}} + \Delta \setminus H_1 \setminus b_{\text{odd}}$. Conversely both generators lie in the original ideal. Reynolds averaging is exact over $\mathbb{C}$, so the invariant quotient has precisely this ideal, including all nilpotents.

The unscaled orbit sums of $s_1^{i_1} \dots s_d^{i_d}$, $0 \leq i_1 \leq \dots \leq i_d \leq d$, give dimension $d(d+1)/2$. The associated graded Hilbert series for the original degree filtration is

$$\sum_{0 \leq i_1 \leq \dots \leq i_d \leq d} z^{i_1 + \dots + i_d} = \frac{(1-z^d)(1-z^{d+1})}{(1-z)(1-z^2)}.$$

No grading of a nonhomogeneous h is asserted.

The original primitive map is explicit:

$$H_0 A_0 + \Delta H_1 A_1 = h(s_1) \frac{A_0 + r A_1}{2} + h(s_2) \frac{A_0 - r A_1}{2}.$$

Its two cochain primitives use $\phi_* \setminus \text{tensor} \setminus F_h$ and $F_h \setminus \text{tensor} \setminus \phi_*$, respectively. The second primitive has a minus sign, matched by the second tensor-differential sign. For a relation of degree M , ordered division followed by swap averaging gives $\deg A_0 \leq M-d$, $\deg A_1 \leq M-d-1$.

The unit $\epsilon_h \setminus \text{tensor} \setminus \epsilon_h$ descends to the invariant algebra and remains in its full jet map. All finite relation quotients and the transitions $M \rightarrow M+1$ commute with Φ . A class killed by the next relation maps to the receiving e -zero, never to external absence.

S6.1.4 4. Push the actual norm to a matrix weight, not a scalar observation

Set

$$w_h(t) = \left| \frac{g(1/2 + it)}{h(1/2 + it)} \right|^2 \frac{1}{2\pi}.$$

The exact real coordinate map is

$$u = t_1 + t_2, \quad v = t_1 - t_2, \quad dt_1 dt_2 = \frac{1}{2} du dv.$$

It gives $S=1+iu$, $\Delta=-v^2$. For

$$P(S, \Delta) = \sum_{a=0}^{\lfloor M/2 \rfloor} \Delta^a f_a(S), \quad \deg f_a \leq M - 2a,$$

define

$$W_{ac}(u) = \frac{(-1)^{a+c}}{2} \int_{\mathbb{R}} v^{2(a+c)} w_h((u+v)/2) w_h((u-v)/2) dv.$$

Then the original arithmetic norm is exactly

$$\|T_h^{(2)} \Phi P\|^2 = \int_{\mathbb{R}} f(1+iu)^* \mathbf{W}(u) f(1+iu) du.$$

Proof: substitute the coordinate map and expand the finite polynomial. Exponential moments justify Fubini. Each finite matrix $W(u)$ is strictly positive: the integrand is the squared modulus of a nonzero polynomial in $-v^2$ against a density positive almost everywhere. The entire nonzero g/h has only discrete zeros on these real lines. The source exponential bound also gives convergence for each fixed u .

Its scalar entry is $(w_h^* w_h)(u)$. Its other entries retain the relative-coordinate moments; they are not replaced by that scalar entry.

For general k retain $S = \sum s_i$, $x_i = s_i$ for $i < k$ and $s_k = S - \sum s_i$. This is a polynomial isomorphism and the real Jacobian is one. Writing $P = \sum x^\alpha f_\alpha(S)$ gives

$$W_{\alpha\beta}(u) = \int_{\mathbb{R}^{k-1}} \prod_{i < k} (1/2 + it_i)^{\alpha_i} \prod_{i < k} (1/2 + it_i)^{\beta_i} \prod_{i < k} w_h(t_i) w_h(u - \sum_{i < k} t_i) d^{k-1}t.$$

The outer coordinate remains $S = k/2 + iu$, and $\deg f_\alpha \leq M - |\alpha|$. This supplies an all- k isometry retaining the entire filtered source. Constants in exponential-moment bounds depend on h, k and the degrees; no uniform tensor bound is inferred.

S6.1.5 5. Canonical control commutes with the descent

For the explicit source-coordinate matrix C and quotient-coordinate matrix U , keep

$$M' = C^* M C, \quad J' = U^{-1} J C, \quad K' = U^{-1} K (U^{-1})^*, \quad G' = U^* G U,$$

$$A' = U^{-1} A U, \quad W' = U^* W U, \quad R' = R U.$$

These follow by substituting into $K = J M^* (-1) J^*$ and the exact constrained-minimum formula. Thus no positive metric has been freely selected. The same isometry carries the actual next relation layer and both boundary maps Y, C_{rel} ; their cross-pairing is unchanged.

There is a further exact base/relative map. Write $w(u) = [m_0, b], [b^*, c_{\text{rel}}]$, with $m_0 > 0$. Then

$$f \mapsto (f_0 + m_0^{-1} b f_{\text{rel}}, f_{\text{rel}})$$

is an isometry into the direct sum weighted by m_0 and $c_{\text{rel}} - b^* m_0^{-1} b$. Its inverse is $(a, z) \mapsto (a - m_0^{-1} b z, z)$. The precise image of the polynomial source is retained; the ratio need not be polynomial. Multiplication by S commutes with this map. Neither the scalar mass nor positivity of this representative norm is substituted for the arithmetic Weil pairing.

S6.1.6 6. Full nilpotent fibres for every tensor degree

For an ordered tuple of roots with orders m_i , the local algebra is

$$L = \mathbb{C}[z_1, \dots, z_k] / (z_i^{m_i}), \quad A = \rho_\Sigma I + N, \quad N = M_{\sum z_i}, \quad D_0 = \sum_i (m_i - 1).$$

Let $c_r = [t^r] \prod_i (1 + t + \dots + t^{(m_i-1)})$, $c_{-1} = 0$. Then the complete module pushforward is

$$\pi_* L \cong \bigoplus_{r=0}^{\lfloor D_0/2 \rfloor} (\mathbb{C}[S]/(S - \rho_\Sigma)^{D_0-2r+1})^{c_r - c_{r-1}}.$$

Proof and maps: on $z_i \wedge^j$ define $F_i = j(m_i - j)z_i \wedge^{(j-1)}$ and $H_i = (2j - (m_i - 1))z_i \wedge^j$. Direct calculation gives $[N, F] = H$, $[H, N] = 2N$, $[H, F] = -2F$. The explicit auxiliary diagonal Gram

$$\|z^\alpha\|_0^2 = \prod_i \frac{\alpha_i! (m_i - 1)!}{(m_i - 1 - \alpha_i)!}$$

makes $F = N^*$. A degree- r primitive p with $Fp = 0$ has ladder length $w+1$, $w = D_0 - 2r$, since

$$FN^j p = j(w - j + 1)N^{j-1}p, \quad \|N^j p\|_0^2 = \frac{j!w!}{(w - j)!} \|p\|_0^2.$$

Orthogonal invariant complements construct all ladders; degree counts give $c_r - c_{(r-1)}$. The actual module map is $[P(S)] \rightarrow P(\rho_\Sigma + N)_p$ on each chosen primitive. This auxiliary Gram is related to the arithmetic one by the explicit operator $G_{\text{arithmetic}}^{(-1)} G_0$; it is used for the algebraic decomposition only. All cross-ladder entries $U^* G_{\text{arithmetic}} U$ remain in control estimates.

For an occupation list n_ρ with sum k , the symmetric component has graded dimensions given by

$$\prod_{\rho} \prod_{j=1}^{n_{\rho}} \frac{1 - t^{m_{\rho} + j - 1}}{1 - t^j}.$$

These are polynomial orbit-count identities, not evaluations of a rational function at roots of unity. Apply the same primitive construction to invariants, with $D_0 = \sum n_\rho (m_\rho - 1)$ and $\rho_\Sigma a = \sum n_\rho \rho$. Central occupation idempotents are retained even when different occupations have the same spectral sum.

For an order-three local input taken twice, the symmetric fibre has ladders

$$1, X, X^2, X^3, X^4, \quad p = z_1^2 - z_1 z_2 + z_2^2, \quad X = z_1 + z_2, \quad Xp = 0.$$

It is $\mathbb{C}[S]/(S - 2\rho)^5$ direct-sum $\mathbb{C}[S]/(S - 2\rho)$, dimension six. This is a local algebra calculation, not an assertion that ζ has a triple zero. The full arithmetic unit commutes with A and carries the ladder coordinates to the original jets.

Each occupation trace is its full dimension times $a^{(\sum n_\rho \rho)}$, with dimension product $\text{binomial}(n_\rho + m_\rho - 1, n_\rho)$. The cochain trace retains $(-1)^k$. Quotienting a top ladder vector, when explicitly requested as a module quotient, makes it the supported zero; the full pushforward itself keeps it.

S6.1.7 7. Exact calibration and scope

For the declared measure $\exp(-t^2/2)dt$, not the arithmetic measure, the three relative directions $1, \Delta, \Delta^2$ give

$$W(u) = \sqrt{\pi} e^{-u^2/4} \begin{pmatrix} 1 & -2 & 12 \\ -2 & 12 & -120 \\ 12 & -120 & 1680 \end{pmatrix}.$$

The unscaled coordinate columns $1, \Delta + 2, \Delta^2 + 12\Delta + 12$ turn this into $\sqrt{\pi} \exp(-u^2/4) \text{diag}(1, 8, 384)$. The full two-variable mass is still 2π . The published core

checker verifies these signs, constants, algebraic primitives, sum resolution and nilpotent blocks. The longer conversation package has a separate 24-method suite, plus independent reruns of the source 18- and 22-method suites; those are not all claimed to be tests in this smaller repository checker.

The new reduction isolates the convolution mass, the relative covariance, and full-jet interpolation on one explicit filtered image. It does not prove their required uniform sublinear tensor estimate. The finite pushforward and matrix-weight model are not asserted to be lisse sheaves on Deligne's Lefschetz pencil. They supply a precisely defined product-to-one-parameter operation to study next, with its adjoint, cohomology, arithmetic trace and original supported relations retained.

References: Stacks Tags 0AVV and 0AWZ; NIST DLMF 18.2; Deligne, La conjecture de Weil II, IHES 52 (1980), 137-252. A bounded supplied French TeX window around 3.2.11–3.2.15 was reread. Its historical line 872 contains an inconsistent numerical implication and is not used as a theorem. No complete new audit of Weil II, analytic integral certificate, Lean execution, or global novelty claim is made.

S7.1 SplitZero: reconstruction, internal homology, and balanced finite jets

Owner-directed formalization continuation, 12 September 2026.

S7.1.1 Scope and provenance

This contribution extends formal/splitzero on the owner's Zeta workbench. Its base is the synchronization PR #5, commit 236f0a8370477991e2d0cf334ad1ebfe4f3f8b17, itself based on the structural PR #4. The original scalar core and all five preceding extension sources remain unchanged. There is no Sneed-side submission or integration in this continuation.

The mathematical source is the owner's SplitZero programme, including the supplied continuation's internal homology and balanced-Mellin sections. The implementation below distinguishes source-derived structure, ordinary reusable algebra, and the new explicit comparison example. It makes no global priority claim and does not treat the number of Lean declarations as a number of mathematical discoveries. No private conversation or source-literature corpus is republished.

The exact build certificate for a revision is the completed SplitZero\derived\constructions workflow on that commit, including direct source checks and its generated AuditDerived.lean. The PR records the accepted execution revision and run. A failed earlier development run is not a certificate for later source.

S7.1.2 1. Reverse reconstruction, with actual scalar action

Let R be a commutative ring, L a join-semilattice with bottom, and let D consist of R -modules V_i with linear transition maps

$$\begin{aligned} \text{rho_ij} &: V_i \rightarrow V_j \quad (i \leq j), \\ \text{rho_ii} &= \text{id}, \quad \text{rho_jk} \circ \text{rho_ij} = \text{rho_ik}. \end{aligned}$$

No finiteness, field, injectivity, or nontriviality assumption is imposed. Construct

$$\text{Total}(D) = \text{disjoint union of } V_i \text{ over } i \text{ in } L.$$

The global zero is $(\text{bottom}, 0)$, and

$$\begin{aligned} (i, x) + (j, y) &= (i \text{ join } j, \text{rho_i, i-join-j}(x) + \text{rho_j, i-join-j}(y)). \\ \text{tau} \cdot (i, x) &= (\text{bottom}, 0). \\ \text{ofR}(r) \cdot (i, x) &= (i, r \cdot x). \end{aligned}$$

`LinearDiagram.totalAddCommMonoid` and `LinearDiagram.totalModule` construct the actual instances and prove every law. For associativity, transport both sides to $i \text{ join } j \text{ join } k$. Linearity and transition composition reduce both to the same three-term sum. The scalar laws follow in the supported case from the R -module laws and in the absent cases from the chosen global zero. The supported-zero scalar sends (i,x) to $(i,0)$.

The bottom fibre is allowed to be nonzero. Specializing it to the zero module recovers the source's carrier consisting of one absent point and the non-bottom fibres. This is an explicit generalization, not an assumption that the bottom fibre in every later dual diagram vanishes. Opposite-index duality itself is not constructed here.

Fixed-index natural families of linear maps produce actual $G(R)$ -linear maps between reconstructed totals. Identity and composition are proved. More substantially, `Recovery.recoverEquiv` reconstructs the intrinsic support fibres of **any** existing $G(R)$ -semimodule M and gives a full $G(R)$ -linear equivalence back to M :

$$(1,x) \mapsto x, \quad m \mapsto (e\ m, m).$$

Its addition proof uses the original absorption identity $m + e\ m = m$. It is not merely a bijection of carriers. A bundled equivalence of the two full categories, including arbitrary changes of support index and both natural inverse comparisons, is a separate library interface not claimed by this implementation.

S7.1.3 2. The internal quotient is characterized by a universal property

Let B_i be transition-stable submodules of V_i . The quotient diagram has fibres V_i/B_i and the genuinely induced quotient transition maps. The projection

$$q : \text{Total}(D) \rightarrow \text{Total}(D/B), \quad q(i,x) = (i,[x])$$

is a surjective $G(R)$ -linear map. The code proves the exact equality criterion

$$q(i,x)=q(i,y) \text{ iff } x-y \text{ is in } B_i.$$

Different labels cannot become equal under q . In particular a relation maps to its own fibre zero.

The main point is stronger than that observation. Let N be **any** $G(R)$ -semimodule, not assumed additively cancellative, and let $f:\text{Total}(D)\rightarrow N$ be split-linear. If

$$f(i,b)=f(i,0) \text{ for every } b \text{ in } B_i,$$

then there exists a unique split-linear $g:\text{Total}(D/B)\rightarrow N$ with $g\ q=f$. The proof does not subtract elements in N . If $x-y$ is in B_i , use the identity $y+(x-y)=x$ inside V_i and then apply additivity of f . This proves constancy on q -fibres. Surjectivity constructs the descended function; linearity and uniqueness follow by lifting representatives.

`Relations.coequalizer_universal` states this against the actual inclusion of the relation diagram and its supported-zero companion. Thus the universal property is proved against arbitrary semimodule targets, not only against a selected class of fixed-support maps. The implementation gives the complete unbundled universal property; it does not merely define the desired quotient and label it a coequalizer.

S7.1.4 3. Actual homology and the exact transported-class kernel

At a degree i of a cochain complex, use the window

$C^{(i-1)} \xrightarrow{d_{\text{Prev}}} C^i \xrightarrow{d_{\text{Next}}} C^{(i+1)}, \quad d_{\text{Next}} d_{\text{Prev}} = 0.$

Window.boundaryToCycles constructs the incoming map into $\ker(d_{\text{Next}})$. Boundaries are its actual linear range, and H is the module quotient of cycles by that range. Window.ofCochain imports these data at every integer degree of a Mathlib CochainComplex; ChainMap.ofCochain imports an actual cochain map without replacing its differentials.

For a chain map $f:C \rightarrow D$, the code constructs

$f_Z : Z(C) \rightarrow Z(D),$
 $H(f) : Z(C)/B(C) \rightarrow Z(D)/B(D).$

It proves identity, composition, and

$H(f)([z]) = 0 \iff \text{there exists } y \text{ with } d_{\text{Prev}_D}(y) = f_i(z).$

Define the module of killed representatives and its original relation submodule:

$\text{Krep} = \{z \text{ in } Z(C) : f_Z(z) \text{ is in } B(D)\},$
 $\text{Bold} = B(C), \text{ viewed as a submodule of Krep.}$

There is a constructed linear equivalence

$\text{Krep}/\text{Bold} \simeq \ker H(f).$

Forward map: the class of z goes to the kernel element $[z]$. It is well-defined because Bold consists exactly of original source boundaries. It is injective because equality of source classes is exactly a difference in Bold. It is surjective because every kernel class has a cycle representative whose image is a boundary. This is ChainMap.homologyKernelEquiv, obtained from a general quotient-kernel equivalence proved in the same file.

The calculation retains actions as well. Given chain endomorphisms a of C and b of D satisfying $f \circ a = b \circ f$, homology_intertwines proves $H(f) \circ H(a) = H(b) \circ H(f)$. kernelAction constructs the restriction of $H(a)$ to $\ker H(f)$. Thus passing to the comparison kernel does not discard a compatible operator or require asserting that the kernel is zero.

S7.1.5 4. Internal homology on the complete support diagram

For coherent support-indexed chain windows, the code constructs the diagrams of preceding terms, middle terms, following terms, cycles, boundaries, and homology. Let R_L denote the reverse reconstruction.

The differential identity is typed as

$R_L(d_{\text{Next}}) \circ R_L(d_{\text{Prev}}) = z_L : R_L(C^{(i-1)}) \rightarrow R_L(C^{(i+1)}),$
 $z_L(1, x) = (1, 0).$

The source and target degrees are explicit. A theorem shows that z_L differs from the constant global-zero map whenever L has a non-bottom element. Cycles satisfy the actual equalizer equation $d(x) = e.d(x)$.

The internal homology projection

$q : R_L(Z(C)) \rightarrow R_L(H(C))$

is the coequalizer of the **original incoming differential into cycles** and its supported-zero companion. `homology_coequalizes` and `homology_coequalizer` establish both parts of that universal property against every split-linear target. This is not an assumed homology compatibility of reconstruction.

For every transition $i \leq j$,

$\text{rho}^{\wedge} H_{ij}([z]) = 0$ iff $\text{rho}_{ij}(z)$ is a boundary at j .

If z is not a boundary at i , its retained class $(i, [z])$ is not $(i, 0)$, regardless of whether that transition kills it. The quotient-kernel equivalence of section 3 computes all such classes as a module, not just a yes/no predicate.

S7.1.6 5. A concrete comparison that detects more than the support labels

Fix any nontrivial commutative ring k . In the displayed degree let

$C: k \xrightarrow{-\theta} k \xrightarrow{-\theta} k,$
 $D: k \xrightarrow{-a} (a, \theta) \xrightarrow{-} k^2 \xrightarrow{-\theta} k.$

Use zero maps in the outside degrees. The two middle chain maps are

$f(a) = (a, \theta),$ $g(a) = (\theta, a).$

The code proves that the source class $[1]$ is nonzero. Its f -image is the **nonzero vector** $(1, 0)$, but that vector is a boundary in D , so $H(f)([1]) = 0$. In fact $H(f) = 0$ on every source class. The g -image $(0, 1)$ cannot be a boundary, because every boundary has second coordinate zero. Hence $H(g)([1])$ is nonzero and $H(f)$ is not $H(g)$.

The ordinary calculation gives $H(C) = k$ and $H(D) = k$ (the latter through second-coordinate projection). These identifications explain the example; the Lean acceptance tests directly prove the nonzero source class, the nonzero chain image, the zero induced map, the surviving class, and the distinction of induced maps rather than relying on a dimension computation.

Consequently the source and target complexes, individual fibre homology, and terminal homology can be identical while the transition kernel differs. This example is parametric over all nontrivial commutative rings, not a finite numerical experiment. Together with the general assembly theorem it supplies an explicit test of the information retained by support-indexed homology. It is an algebraic test case, not a claimed model of the global theta comparison.

S7.1.7 6. Balanced finite jets, including the original split quotient square

Let k and B be commutative rings and fix a $k[t]$ -algebra structure on B . Let $u: k[t] \rightarrow B$ denote that map and

$I_-(\text{rho}, m) = ((t - \text{rho})^{\wedge} m), \quad m \geq 0.$

There is an explicit B -algebra equivalence

$B \otimes_{k[t]} (k[t]/I_-(\text{rho}, m)) \simeq B / ((u(t) - u(\text{rho}))^{\wedge} m).$

It maps $b \otimes [p]$ to $[u(p)b]$, with inverse $[b]$ to $b \otimes 1$. No flatness assumption is used for this quotient base-change theorem. This is a specialization of the existing Mathlib theorem `Algebra.tensorProduct.quotIdealMapEquivTensorQuot`, not a claim to have independently developed general tensor-product quotient theory.

splitBaseChange lifts this equivalence to the original G-construction on both sides and proves the commutative square with reflect. It preserves τ and e separately and is a genuine semiring equivalence, not just an amplitude comparison. Thus every element of the finite-jet quotient has an inverse image before forgetting split support.

For any $k[t]$ -module V and v in V , the exact balancing calculation is

$$(1-u(t)) \text{ tensor } (t.v) - u(t) \text{ tensor } (v-t.v) = 0.$$

Expanding gives $1 \text{ tensor } (t.v) - u(t) \text{ tensor } v$, which vanishes by the tensor balancing relation. This is the algebraic equation of the source's Mellin repair. The choice $u(t)=s$ and $t.v=Dv$ is an application once those analytic module structures and intertwining maps have been constructed. It does not assert that the entire global balanced kernel vanishes, or that analytic scalar extension is flat without proof.

S7.1.8 7. Where Deligne enters the intended RH route

None of sections 1-6 imports a Deligne purity theorem. They provide the algebraic maps with which a proposed realization can now be specified and its kernel retained.

For this programme, the subsequent dependency diagram should distinguish the following mathematical obligations:

1. Construct the actual operator-balanced theta complex at the relevant support labels, and its action-compatible analytic comparison β to the spectral sheaf $\mathcal{O}/(2\xi)$. Identify its kernel or cone using the same maps; a finite-jet isomorphism is not a global injectivity argument.
2. Construct the geometric compact-support and ordinary complexes, their actual comparison c , their correspondence action, and a compatible realization identifying the required spectral sheaf with the image of $H^1(c)$. Any additional kernel/cone contributions to the trace must be kept or proved to vanish.
3. Establish two-sided weight control on that **same image**. In Deligne's geometric setting the compact-support upper estimate and the duality-derived ordinary-cohomology lower estimate meet on the image. The dualizing operation, degree and Tate twists, tensor-power maps, and hypotheses of the estimates are part of this step, not consequences stipulated in the definition of support.
4. Transport the spectral normalization without changing the arithmetic function. For a dilation parameter $a>1$, an eigenvalue a^ρ has modulus $a^{(\text{Re } \rho)}$. A proved weight-one modulus $a^{(1/2)}$, for the representation identified with every relevant spectral zero, then forces $\text{Re } \rho=1/2$. This last calculation does not supply the missing weight estimate; it states the precise final implication of this route.

These are dependencies of the specified route, not a claim that every possible proof of RH must follow it. The newly implemented kernel action is useful in steps 1-2 precisely because it keeps the part killed by a comparison available to the operator and trace calculation.

The supplied Connes-Consani article has an actual quotient-sheaf realization with a specified closure and scaling action. Its Theorem 1.2 realizes **critical zeros**. That theorem alone cannot be substituted for an identification representing all nontrivial zeros in the desired purity argument. This is a concrete source/target distinction for a future comparison map, not a dismissal of the construction.

S7.1.9 8. Reading record and references

The six supplied S20 chunks were checked against their individual declared hashes and concatenated in order. The resulting archive has 216,580,466 bytes, 312 members, and SHA-256

e2005bf31e1fcf362765f73c315c855e0f504f24f34d3a0ab188049da522b7c8.

The current top-level readers/english_standalone.html and readers/source_language.html were used for the selected readings, not the nested zero-accepted salvage corpus. The inspected windows include the tensor-square improvement in 3.2.13, the upper-bound statement in 3.3.1, and the duality/image argument in 3.3.4-3.3.6. This is not an independent audit of every page or of the entire historical proof. The Connes-Consani introduction and Theorem 1.2 were read in the supplied volume, printed pages 83-85 (physical PDF pages 94-96). No copyrighted source corpus is included in this contribution.

S8.1 Coherent arithmetic interpolation and joint tensor boundary control

Owner-directed continuation, 12 September 2026. Written mathematical arguments for review; the new analytic and matrix results in this note have not been Lean-checked.

S8.1.1 0. Accepted inputs and the change in the continuation

The new formalization receipt reports—and the repository metadata and workflow step summaries confirm—a successful check at 5d2772ea0a16d177ac3e01ff70394b90ba95a232 in PR #12. That certificate covers the specified retraction’s algebraic/topological consequences, the complete coefficient homotopy family, and the stated finite-chart dual maps. It does not certify the analytic construction of the theta retraction, support-changing synchronization homotopies, or the matrix estimates developed here. Its branch is left untouched.

The second attachment proves, for an unrestricted finite correction matrix B , the exact formula

$$G_B = G_{\perp,m} + (B + H_m^{-1}C_m)^* H_m (B + H_m^{-1}C_m). \quad (0.1)$$

Once $m+1 \geq \dim E_Z$, every positive metric ray is realized by an actual theta-boundary correction, with the arithmetic jets unchanged. Its further conclusion

$$\inf_B \epsilon_A(G_B) = \max_{\rho \in \mathbb{Z}} |2\Re \rho - 1| \quad (0.2)$$

therefore has to be retained. This note does not count unrestricted metric optimization as a new arithmetic estimate. It instead uses the unique least-norm representative for a fixed, increasing space of the original arithmetic boundaries. It proves compatibility of these representatives for all finite packets, an exact full-jet moment-matrix formula, and a joint total-degree tensor construction.

All conclusions are derived on the existing characteristic-zero theta complex over the marked tau-base. None is asserted to be an application of finite-field purity to a space merely renamed tau.

S8.1.2 1. Fixed scalar, cochain, and arithmetic maps

Retain the original scalar construction

$$G(R) = \{\tau\} \sqcup \{r^\bullet : r \in R\}, \quad e_R = 0_R^\bullet,$$

and the entire square

$$\boxed{\begin{array}{ccc} G(\mathbb{Z}) & \xrightarrow{G(j)} & G(\mathbb{C}) \\ p_{\mathbb{Z}} \downarrow & & \downarrow p_{\mathbb{C}} \\ \mathbb{Z} & \xrightarrow{j} & \mathbb{C}. \end{array}} \quad (1.1)$$

The target of $p_{\mathbb{Z}}$ is infinite. This quotient remains part of the marked geometry over $\mathfrak{b}_\tau$. Coefficient maps below fix external absence and carry a represented scalar zero to the represented scalar zero of the target.

Use the unchanged spaces

$$V = \{\phi \in \mathcal{S}(\mathbb{R}) : \phi \text{ even}, \phi(0) = 0, \int_{\mathbb{R}} \phi = 0\},$$

$$\mathcal{B} = \{F \in C^\infty(\mathbb{R}_{>0}) : \sup_{x>0} x^b |D^k F(x)| < \infty \forall b \in \mathbb{Z}, k \geq 0\}, \quad D = -x\partial_x,$$

$$\Theta\phi(x) = \sum_{m \neq 0} \phi(mx), \quad C_+ = [V \xrightarrow{\Theta} \mathcal{B}], \quad Q = \mathcal{B}/\Theta V.$$

The complex is in degrees 0, 1. Write $q : \mathcal{B} \rightarrow Q$. Its action is by the original D , not a shifted operator. Let

$$\mathcal{M}F(s) = \int_0^\infty F(x) x^s \frac{dx}{x}, \quad \phi_*(x) = (4\pi^2 x^4 - 6\pi x^2) e^{-\pi x^2}, \quad f_0 = \Theta\phi_*,$$

$$g(s) = 2\xi(s) = s(s-1)\pi^{-s/2}\Gamma(s/2)\zeta(s), \quad \mathcal{M}f_0 = g. \quad (1.2)$$

The established range identities are used with these exact constants. They give $\mathcal{M}\Theta\phi = gH_\phi$, with H_ϕ entire. In particular every finite jet map used below annihilates ΘV .

For $n \geq 0$, retain

$$V_n = \text{span}\{\phi_*, D\phi_*, \dots, D^n\phi_*\}, \quad L_n = \Theta V_n,$$

$$Q_n = \mathcal{B}/L_n \longrightarrow Q_{n+1}, \quad \ker = L_{n+1}/L_n. \quad (1.3)$$

Their split reconstructions have labels V_n . The transport of a class in L_{n+1}/L_n is the supported zero at V_{n+1} ; it is not external absence. The derivative has type $Q_n \rightarrow Q_{n+1}$ because $DL_n \subseteq L_{n+1}$.

S8.1.3 2. A polynomial presentation of the actual finite representatives

Take a nonempty finite set Z of actual zeros of g , with their complete orders m_ρ , and put

$$h(t) = \prod_{\rho \in Z} (t - \rho)^{m_\rho}, \quad d = \deg h, \quad E_h = \mathbb{C}[t]/(h), \quad v_h(s) = g(s)/h(s). \quad (2.1)$$

The polynomial variable t acts on the source by D and is evaluated at s by Mellin transformation. Full orders make v_h nonzero at all selected centres. Let j_h be the complete Hermite-jet/Chinese-remainder map into E_h and retain

$$v_h = j_h v_h \in E_h^\times, \quad \varepsilon_h = v_h^{-1}. \quad (2.2)$$

The unit ε_h is not the scalar e . Its split scalar is $\varepsilon_h^\bullet$.

There is an actual $F_h \in \mathcal{B}$ with $h(D)F_h = f_0$ and $\mathcal{M}F_h = v_h$. It can be obtained successively from

$$S_\rho F(x) = x^{-\rho} \int_x^\infty F(y) y^{\rho-1} dy, \quad (D - \rho)S_\rho F = F, \quad (2.3)$$

whenever the required Mellin value vanishes. At zero, replace the integral by its negative from 0 to x , using that vanishing; at infinity use the displayed integral. The defining estimates of $\mathcal{B}$ prove rapid decay of every scaling derivative at both ends. Repeated zero jets permit iteration. Uniqueness follows from injectivity of Mellin and $h\mathcal{M}F = 0 \Rightarrow F = 0$.

Define the linear map

$$\boxed{\mathcal{T}_h : \mathbb{C}[t] \longrightarrow \mathcal{B}, \quad P \longmapsto P(D)F_h.} \quad (2.4)$$

It is injective and satisfies

$$\mathcal{M}\mathcal{T}_h(P) = \frac{g}{h}P, \quad \mathcal{T}_h(hP) = \Theta(P(D)\phi_*), \quad J_h\mathcal{T}_h(P) = v_h[P]_h. \quad (2.5)$$

Here $J_h F = j_h \mathcal{M}F$. The first equation retains the whole completed function, not its values only on the critical line.

For $N = n + d$, let $\mathcal{P}_N = \mathbb{C}[t]_{\leq N}$, and define

$$\mathcal{J}_{h,N} : \mathcal{P}_N \twoheadrightarrow E_h, \quad P \longmapsto v_h[P]_h.$$

Its exact sequence is

$$\boxed{0 \longrightarrow \mathcal{P}_n \xrightarrow{\times h} \mathcal{P}_{n+d} \xrightarrow{\mathcal{J}_{h,n+d}} E_h \longrightarrow 0.} \quad (2.6)$$

Applying $\mathcal{T}_h$ sends the left map to the original theta relations L_n . Thus its split internal quotient has exactly the relation $P - P' \in h\mathcal{P}_n$, with the support label retained.

The original source section is

$$s_h(u) = \mathcal{T}_h(\text{rem}_h(\varepsilon_h u)), \quad J_h s_h = 1, \quad q s_h = \sigma_h. \quad (2.7)$$

No arbitrary metric or section has entered (2.6).

S8.1.4 3. Exact arithmetic moment matrices and the full-jet interpolation formula

The Hilbert observation is $\mathcal{H} = L^2((0, \infty), dx)$. The precise transform map is

$$\mathcal{H} \xrightarrow{\mathcal{L}} L^2(\mathbb{R}, dy) \xrightarrow{\mathcal{F}_+} L^2(\mathbb{R}, dt/(2\pi)),$$

$$\mathcal{L}F(y) = e^{y/2}F(e^y), \quad \mathcal{F}_+\psi(t) = \int_{\mathbb{R}} \psi(y)e^{ity}dy, \quad (\mathcal{F}_+\mathcal{L}F)(t) = \mathcal{M}F(\tfrac{1}{2} + it). \quad (3.1)$$

Both arrows are unitary with these measures. The inverse Fourier factor is $1/(2\pi)$; no mass of a measure below is set equal to one. The same map carries D to multiplication by $s_t = 1/2 + it$.

Define the finite positive measure

$$d\nu_h(t) = \left| \frac{g(\frac{1}{2} + it)}{h(\frac{1}{2} + it)} \right|^2 \frac{dt}{2\pi}. \quad (3.2)$$

Any apparent singularity at a selected critical-line zero is removed by the entire function v_h . All moments are finite. In the fixed basis $1, t, \dots, t^N$ of $\mathcal{P}_N$, put

$$(M_{h,N})_{ij} = \int_{\mathbb{R}} \overline{s_t^i} s_t^j d\nu_h(t), \quad 0 \leq i, j \leq N. \quad (3.3)$$

In the integrand t is the real integration variable; the polynomial basis is evaluated at s_t . This prevents the polynomial variable from being confused with the spectral-height coordinate.

The matrix $M_{h,N}$ is positive definite. A polynomial with zero norm vanishes almost everywhere on a line on which v_h is nonzero almost everywhere, hence is zero. Write $J_{h,N}$ for the matrix of $\mathcal{J}_{h,N}$ in the fixed quotient basis $1, t, \dots, t^{d-1}$. It includes multiplication by the actual unit v_h .

Set

$$\mathcal{C}_{h,N} = J_{h,N} M_{h,N}^{-1} J_{h,N}^*, \quad C_{h,N} = M_{h,N}^{-1} J_{h,N}^* \mathcal{C}_{h,N}^{-1}. \quad (3.4)$$

These are finite matrices on declared coordinate spaces. $J_{h,N} C_{h,N} = 1$. The actual test-function map is

$$R_{h,n} = \mathcal{T}_h C_{h,n+d} : E_h \longrightarrow \mathcal{B}. \quad (3.5)$$

Theorem. This is precisely the preceding orthogonal representative $(1 - P_n)s_h$, where P_n is the $L^2(dx)$ orthogonal projection onto L_n . In particular,

$$qR_{h,n} = \sigma_h, \quad J_h R_{h,n} = 1, \quad G_{h,n} := R_{h,n}^* R_{h,n} = \mathcal{C}_{h,n+d}^{-1}. \quad (3.6)$$

Proof. Every polynomial with jet u is $C_{h,N}u + z$ with $J_{h,N}z = 0$. The cross term vanishes because

$$z^* M_{h,N} C_{h,N} u = z^* J_{h,N}^* \mathcal{C}_{h,N}^{-1} u = 0.$$

Its norm is therefore $u^* \mathcal{C}_{h,N}^{-1} u + z^* M_{h,N} z$. This proves the unique minimizer. By (2.6), its difference from the degree-below- d lift (2.7) is exactly a member of L_n . It must be $(1 - P_n)s_h$. This also proves (3.6).

Thus the subtraction-of-nearby-Grams formula of the previous note has the exact alternative (3.6): invert the full-jet interpolation matrix. This is a matrix-valued Christoffel construction with the arithmetic local unit retained. The finite least-norm identity itself is standard linear algebra; its application here identifies the actual original representative, source relation, and completed multiplier.

For one simple zero ρ , the same formula is

$$G_{\rho,n} = \frac{1}{|g'(\rho)|^2 \mathcal{K}_{\nu_{\rho,n+1}}(\rho, \rho)}, \quad \mathcal{K}_{\nu,N}(z, w) = (1, z, \dots, z^N) M_N^{-1} (1, w, \dots, w^N)^*. \quad (3.7)$$

The complex conjugate in the second evaluation is part of the displayed kernel. Higher orders use (3.4), not just point evaluations. The factor $g' = 2\xi'$ is retained.

S8.1.5 4. All finite packets fit the same source filtration

Let $h \mid H$ be polynomials for nested packets with full orders and set $m = H/h$. Since the newly added centres are disjoint, h and m are coprime. There is a $\mathbb{C}[t]$ -linear CRT injection

$$\iota_{hH} : E_h \hookrightarrow E_H,$$

which inserts zero jets at the new centres. It is multiplication by the appropriate CRT idempotent after lifting a residue; it sends the unit of E_h to that idempotent, so it is not being asserted to be a unital ring map.

The polynomial map $P \mapsto mP$ has the exact properties

$$\mathcal{T}_H(mP) = \mathcal{T}_h(P), \quad J_H \mathcal{T}_h(P) = \iota_{hH} \mathcal{J}_h(P), \quad (4.1)$$

and is isometric from ν_h to ν_H because $|v_H mP| = |v_h P|$. The CRT equations and degree bounds prove

$$s_H \iota_{hH} = s_h.$$

The original L_n is independent of the packet, so

$$\boxed{R_{H,n} \iota_{hH} = R_{h,n}, \quad \iota_{hH}^* G_{H,n} \iota_{hH} = G_{h,n}, \quad \iota_{hH}^* W_{H,n} \iota_{hH} = W_{h,n}.} \quad (4.2)$$

The action also intertwines: $A_H \iota_{hH} = \iota_{hH} A_h$, where $A_h = M_t$. Thus a certificate on the larger packet restricts by this actual congruence to the smaller packet. The inverse interpolation matrices satisfy the corresponding inverse-compression formula; inverse and compression are not commuted.

The finite sections consequently glue on the algebraic direct limit of the actual packet injections. This statement does not assert convergence of an infinite sum of packet projectors or identify the whole Q with that direct limit.

At every support label, lift these maps as $(\lambda, u) \mapsto (\lambda, \iota_{hH} u)$ and $(\lambda, u) \mapsto (\lambda, R_{h,n} u)$. Added zero jets remain represented zeros. The label map in (1.3) is still the map that admits one more source relation.

S8.1.6 5. A global density result, with its precise cohomological consequence

The single derivative family $\{D^n f_0 : n \geq 0\}$ is already dense in $\mathcal{H}$.

Proof. Put $d\nu(t) = |g(1/2 + it)|^2 dt / (2\pi)$. It has an exponential moment of every order $c < \pi/2$. To verify this, the alternating-series formula and partial summation give

$$|\zeta(\tfrac{1}{2} + it)| \leq \frac{2|\tfrac{1}{2} + it|}{\sqrt{2} - 1}.$$

The gamma vertical-line asymptotic gives, for sufficiently large $|t|$,

$$|g(\tfrac{1}{2} + it)|^2 \leq C(1 + |t|)^{11/2} e^{-\pi|t|/2}.$$

The constant C is a fixed bound, not a numerical enclosure claimed here. The gamma fact used is NIST DLMF 5.11.9. The same exponential-moment property holds for ν_h , since v_h is entire at the finitely many possible denominator zeros and has polynomially modified tails.

If $f \in L^2(\nu)$ is orthogonal to every polynomial, the finite measure $\bar{f} d\nu$ has a holomorphic Fourier transform in a nonempty horizontal strip, by Cauchy–Schwarz and the exponential moment. All

derivatives at the origin vanish. Analytic uniqueness makes its transform zero; Fourier uniqueness for finite measures makes the measure zero. Thus polynomials are dense in $L^2(\nu)$.

Multiplication by the actual function $g(1/2 + it)$ is a unitary map $L^2(\nu) \rightarrow L^2(dt/(2\pi))$: its inverse divides by g away from its measure-zero set of real-line zeros. The inverse is a map of weighted L^2 spaces, not holomorphic division through an arithmetic zero. Combining it with (3.1) sends polynomials to $P(D)f_0$. This proves the assertion.

It follows for each fixed packet that

$$\boxed{G_{h,n} \longrightarrow 0 \quad \text{in every matrix entry and in operator norm.}} \quad (5.1)$$

Indeed $P_n \rightarrow 1$ strongly on $\mathcal{H}$, and the finite number of columns of s_h is fixed. Since each $G_{h,n}$ is positive definite, the least eigenvalue of its inverse tends to infinity. Every nonzero arithmetic row functional $\ell : E_h \rightarrow \mathbb{C}$ therefore has

$$\boxed{\|\ell\|_{G_{h,n}^\vee}^2 = \ell \mathcal{C}_{h,n+d} \ell^* \longrightarrow \infty.} \quad (5.2)$$

These facts do not kill a cohomology class. The actual maps are

$$\mathcal{B}/L_n \longrightarrow \mathcal{H}/L_n, \quad Q = \mathcal{B}/\Theta V \longrightarrow \mathcal{H}/\overline{\Theta V}^{\mathcal{H}} = 0. \quad (5.3)$$

The first map is injective because L_n is finite-dimensional and consists of the same smooth functions in both spaces. The second map forgets the stronger topology and has the whole Q as kernel. Its split lift lands at the represented zero in $G(0)$, not at τ . $G(0)$ retains both elements. An active class may therefore tend to zero under the L^2 observation while remaining fixed by $qR_{h,n} = \sigma_h$ and $J_h R_{h,n} = 1$.

The constructive consequence is to estimate relative boundary flux against the complete interpolation cost (3.4), not to use the absolute smallness of $G_{h,n}$ as a weight bound.

S8.1.7 6. Tail representation and same-metric reflection control

Retain the unscaled orthogonal vectors from the previous calculation:

$$u_0 = f_0, \quad u_n = (1 - P_{n-1})D^n f_0, \quad \mathfrak{h}_n = \|u_n\|^2, \quad (6.1)$$

$$Du_n = u_{n+1} + \frac{1}{2}u_n - \frac{\mathfrak{h}_n}{\mathfrak{h}_{n-1}}u_{n-1} \quad (n \geq 1).$$

The diagonal $1/2$ and the negative last coefficient follow from $D^* = 1 - D$ on these functions. Neither the u_n nor their norms are rescaled. Define $r_n = \mathfrak{h}_n^{-1}u_n^* s_h$. The new density result makes the entire tail formula exact:

$$\boxed{G_{h,n} = \sum_{j>n} \mathfrak{h}_j r_j^* r_j.} \quad (6.2)$$

This series converges in finite matrix norm. Its source map is $u \mapsto (r_j u)_{j>n}$ into the weighted sequence space with norm $\sum_{j>n} \mathfrak{h}_j |c_j|^2$. The map retains every coefficient; it is an isometry for $G_{h,n}$.

The previous boundary calculation, or telescoping (6.1), gives

$$\boxed{W_{h,n} = A_h^* G_{h,n} + G_{h,n} A_h - G_{h,n} = \mathfrak{h}_{n+1}(r_{n+1}^* r_n + r_n^* r_{n+1}).} \quad (6.3)$$

It pairs two explicit maps into L_{n+1}/L_n . At the original support V_n the derivative defect is $-[u_{n+1}]r_n$; at V_{n+1} it becomes the supported zero. This is also the input to the now-checked coefficient homotopy family, with $\kappa_n = K_n J_h$ and $\kappa_n \Theta = 0$.

For a reflection-stable packet define the actual antilinear involution

$$j_h u(s) = \overline{u(1 - \bar{s})} \pmod{h}.$$

On functions use $j_B F(x) = x^{-1} \overline{F(1/x)}$. It is antiunitary on $\mathcal{H}$ and satisfies $Dj_B = j_B(1 - D)$. The specific section (2.7) satisfies $j_B s_h = s_h j_h$: since $h^\dagger = (-1)^d h$, both the unit and the numerator have the corresponding $(-1)^d$ factor. Also $j_B L_n = L_n$, so uniqueness of orthogonal projection gives $j_B R_{h,n} = R_{h,n} j_h$.

Write $j_h u = C_h \bar{u}$ in the retained coordinates. Then

$$\boxed{C_h^* G_{h,n} C_h = \overline{G_{h,n}}, \quad A_h C_h = C_h (I - \overline{A_h}), \quad C_h^* W_{h,n} C_h = -\overline{W_{h,n}}.} \quad (6.4)$$

Consequently the generalized spectrum of $(W_{h,n}, G_{h,n})$ is symmetric under $\lambda \mapsto -\lambda$ **for this same canonical metric**, with full multiplicities retained. An upper inequality $W_{h,n} \preceq \epsilon G_{h,n}$ therefore implies the lower inequality $W_{h,n} \succeq -\epsilon G_{h,n}$ by applying j_h to the input vector.

The residue duality is still the separate explicit morphism with matrix S_h , and its pulled-back metric is $S_h^* G_{h,n}^{-1} S_h$. The relation to the current metric is the linear map $G_{h,n}^{-1} S_h$ into its antilinear dual coordinates. The arithmetic Weil form remains $S_h J_g$; no positivity is supplied merely by (6.4).

For completeness, retain the full rank-two formula

$$a_n = r_n G_{h,n}^{-1} r_n^*, \quad b_n = r_{n+1} G_{h,n}^{-1} r_{n+1}^*, \quad c_n = r_n G_{h,n}^{-1} r_{n+1}^*.$$

The least control excess is

$$\epsilon_{h,n} = \mathfrak{h}_{n+1} \left(|\Re c_n| + \sqrt{a_n b_n - (\Im c_n)^2} \right). \quad (6.5)$$

For reflection-stable Z , the additional proved identity is $\Re c_n = 0$: take the trace of $G_{h,n}^{-1} W_{h,n}$, which is $2\Re \operatorname{Tr} A_h - d = 0$. Thus (6.5) also equals $\mathfrak{h}_{n+1} \sqrt{a_n b_n - (\Im c_n)^2}$. Both equations are retained. Equation (3.6) supplies every occurrence of $G_{h,n}^{-1}$ without a difference of nearly equal Gram matrices.

S8.1.8 7. Joint total-degree control on the actual product complex

The tensor degree will be denoted k , independently of the relation degree n and the packet multiplicities. Put

$$E_h^{(k)} = E_h^{\otimes k}, \quad A_h^{(k)} = \sum_{j=1}^k I^{\otimes(j-1)} \otimes A_h \otimes I^{\otimes(k-j)}.$$

The existing product complex over $\mathfrak{b}_\tau$ has differential

$$d(x_1 \otimes \cdots \otimes x_k) = \sum_j (-1)^{\sum_{i < j} |x_i|} x_1 \otimes \cdots \otimes dx_j \otimes \cdots \otimes x_k.$$

Define $\mathcal{P}_M^{(k)} = \mathbb{C}[t_1, \dots, t_k]_{\text{total degree} \leq M}$ for $M \geq k(d-1)$ and

$$\mathcal{T}_h^{(k)} P = P(D_1, \dots, D_k) (F_h^{\otimes k}). \quad (7.1)$$

Its Mellin transform is $P(s_1, \dots, s_k) \prod_j g(s_j)/h(s_j)$. Its full jet map $J_{k,M}$ is reduction modulo each $h(t_j)$ followed by multiplication by $v_h^{\otimes k}$. The target is $E_h^{(k)}$ and this map is surjective. The tensor remainder basis has total degree at most $k(d-1)$.

The exact relation space is

$$\mathcal{I}_{k,M} = \mathcal{P}_M^{(k)} \cap (h(t_1), \dots, h(t_k)). \quad (7.2)$$

Polynomial division in the fixed order $t_1, \dots, t_k$ represents each member as $\sum_j h(t_j)P_j$, with $\deg P_j \leq M-d$. It terminates because every h is monic and replacing a leading power lowers total degree. Under (7.1), each term is an actual top cochain boundary: in the j -th source factor use ϕ_* in place of F_h and give its primitive the factor $(-1)^{j-1}$. The differential contributes the second $(-1)^{j-1}$. The resulting boundary is $+h(t_j)P_j$ with no removed sign.

Thus these joint corrections are maps in the original product complex, not freely chosen positive tensor metrics. Set $\mathcal{B}_{k,M} = \mathcal{T}_h^{(k)} \mathcal{I}_{k,M}$.

The moment matrix on the monomials of total degree at most M is

$$(M_{k,M})_{\alpha\beta} = \prod_{j=1}^k \int \overline{s_t^{\alpha_j}} s_t^{\beta_j} d\nu_h(t). \quad (7.3)$$

Its positive definiteness follows because a polynomial cannot vanish almost everywhere on the full real product unless it is zero. It is a principal submatrix of the stated product moment matrix, not a declaration that the total-degree space is a tensor product of smaller univariate spaces.

The actual joint least-norm representative and its metric are

$$R_{k,M} = \mathcal{T}_h^{(k)} M_{k,M}^{-1} J_{k,M}^* (J_{k,M} M_{k,M}^{-1} J_{k,M}^*)^{-1},$$

$$G_{k,M} = (J_{k,M} M_{k,M}^{-1} J_{k,M}^*)^{-1}. \quad (7.4)$$

The proof is the same explicit constrained-minimum calculation as (3.6), now with the relation ideal (7.2). In particular its arithmetic class is exactly $\sigma_h^{\otimes k}$ and every jet is fixed.

For a rectangular degree budget N one has the actual inclusion

$$\mathcal{P}_N^{\otimes k} \hookrightarrow \mathcal{P}_{kN}^{(k)}.$$

It carries the old product representative into the feasible set of the new problem. Therefore

$$G_{k,kN} \preceq G_{h,N-d}^{\otimes k} \quad (N \geq d). \quad (7.5)$$

This is an inequality from an inclusion of admissible original boundaries. It is not asserted to imply the same ordering of control forms, whose dependence on A is retained separately.

S8.1.9 8. The product error is one new total-degree layer

Let $\mathcal{H}_k = L^2(\mathbb{R}_{>0}^k, d^k x)$, and let $P_{\mathcal{B}_{k,M}}$ be its orthogonal projection onto the finite-dimensional actual boundary space. With the fixed low-degree section $s_h^{\otimes k}$,

$$R_{k,M} = (1 - P_{\mathcal{B}_{k,M}}) s_h^{\otimes k}.$$

Put

$$\mathcal{E}_{k,M} = (1 - P_{\mathcal{B}_{k,M}})\mathcal{B}_{k,M+1}.$$

Because the jet map is already onto at both degrees,

$$\dim \mathcal{E}_{k,M} = \binom{M+k}{k-1}. \quad (8.1)$$

This is $\dim \mathcal{P}_{M+1}^{(k)} - \dim \mathcal{P}_M^{(k)}$; the d^k jet constraints cancel from the dimension difference.

Let $D^{(k)} = \sum_j D_j$. Its induced action on jets is $A_h^{(k)}$. The actual derivative defect lies in $\mathcal{B}_{k,M+1}$:

$$B_{k,M} = D^{(k)} R_{k,M} - R_{k,M} A_h^{(k)}.$$

Define the two explicitly typed maps into the same new relation layer

$$Y_{k,M} = P_{\mathcal{E}_{k,M}} R_{k,M} : E_h^{(k)} \rightarrow \mathcal{E}_{k,M},$$

$$C_{k,M} = (1 - P_{\mathcal{B}_{k,M}}) B_{k,M} : E_h^{(k)} \rightarrow \mathcal{E}_{k,M}.$$

Integration by parts gives $(D^{(k)})^* + D^{(k)} = kI$ on these functions. Orthogonality then proves

$$W_{k,M} := (A_h^{(k)})^* G_{k,M} + G_{k,M} A_h^{(k)} - k G_{k,M} = -(Y_{k,M}^* C_{k,M} + C_{k,M}^* Y_{k,M}), \quad (8.2)$$

$$G_{k,M} - G_{k,M+1} = Y_{k,M}^* Y_{k,M}, \quad \text{rank } W_{k,M} \leq 2 \binom{M+k}{k-1}. \quad (8.3)$$

For (8.3), use the orthogonal decomposition $\mathcal{B}_{k,M+1} = \mathcal{B}_{k,M} \oplus \mathcal{E}_{k,M}$. Its projection sends $R_{k,M}$ to $Y_{k,M}$ and the new representative is $R_{k,M} - Y_{k,M}$.

The source quotient map is the same degree transport as before:

$$\mathcal{B}_{k,M+1}/\mathcal{B}_{k,M} \xrightarrow{\sim} \mathcal{E}_{k,M}, \quad [z] \mapsto (1 - P_{\mathcal{B}_{k,M}})z.$$

A derivative class in this kernel becomes the supported zero only at the next total-degree label. The primitive retains which tensor factor supplied the theta boundary and its cochain sign. Synchronization by $(1, e)$ in each required two-leg factor supplies the common joint support, while the original mask remains recorded.

Thus the product estimate need not simply copy k identical one-factor errors: (8.2) gives a new jointly optimized boundary-layer expression with completely specified moment data and maps. Its rank bound alone does not bound its generalized eigenvalues.

S8.1.10 9. Same-metric reflection and residue duality on the product

For a reflection-stable packet, $j_h^{\otimes k}$ is the antilinear involution on $E_h^{(k)}$, defined on pure tensors by applying j_h to every factor. The corresponding function reflection is $F(x_1, \dots, x_k) \mapsto \prod_j x_j^{-1} \overline{F(x_1^{-1}, \dots, x_k^{-1})}$.

It preserves both the total-degree numerator space and its relation ideal. Since $(g/h)^\dagger = (-1)^d (g/h)$, its action on a numerator is $(-1)^{kd} P^\dagger$; this factor is retained. Uniqueness of the minimum in (7.4) proves reflection compatibility of $R_{k,M}$. Therefore the analogue of (6.4) gives symmetry of the generalized spectrum of $(W_{k,M}, G_{k,M})$ on the same metric.

Residue duality remains the explicitly specified map with matrix $S_h^{\otimes k}$ and target line $\mathcal{L}_k$, on which dilation acts by a^k . It satisfies

$$(A_h^{(k)})^* S_h^{\otimes k} + S_h^{\otimes k} A_h^{(k)} = k S_h^{\otimes k}.$$

Any fixed degree-orientation scalar in the cochain evaluation is retained separately; the ordered product of the scalar residue pairings here has matrix exactly $S_h^{\otimes k}$.

Its dual metric and control are

$$\begin{aligned} G_{k,M}^D &= (S_h^{\otimes k})^* G_{k,M}^{-1} S_h^{\otimes k}, \\ W_{k,M}^D &= -(S_h^{\otimes k})^* G_{k,M}^{-1} W_{k,M} G_{k,M}^{-1} S_h^{\otimes k}. \end{aligned} \quad (9.1)$$

The Jacobian contraction is still the original multiplication trace, with every multiplicity, and is unchanged by the source boundaries used to construct (7.4). Neither (9.1) nor reflection alone establishes an arithmetic upper bound.

S8.1.11 10. Quantitative certificate and the Deligne comparison

For one or several variables write M for the positive moment matrix, J for its fixed full-jet map, and $\mathcal{C} = JM^{-1}J^*$. These actual matrices now replace an unrestricted metric search.

A useful deterministic enclosure is as follows. Suppose a Hermitian approximation $\widehat{M}$ has a verified bound $\|M - \widehat{M}\| \leq \eta$ and $\widehat{M} \succeq \mu I$ for a retained $\mu > \eta$. Then

$$\|M^{-1} - \widehat{M}^{-1}\| \leq \frac{\eta}{\mu(\mu - \eta)}, \quad \|\mathcal{C} - J\widehat{M}^{-1}J^*\| \leq \|J\|^2 \frac{\eta}{\mu(\mu - \eta)}. \quad (10.1)$$

This is the resolvent identity for inverses. The positive lower bound on $\mathcal{C}$ must also be retained before a second inversion. With $\widehat{G}$ and $\widehat{W}$ and verified errors η_G, η_W , the sufficient matrix certificate is

$$\widehat{G} - \eta_G I \succ 0, \quad \epsilon \widehat{G} \pm \widehat{W} - (\epsilon \eta_G + \eta_W) I \succeq 0. \quad (10.2)$$

No numerical interval enclosure for the actual infinite arithmetic moments is claimed merely from a floating-point calculation. The previous exterior-theta sums give another exact representation of their one-variable inputs; all tails and roundoff must be supplied to (10.1).

Deligne's retained Corollaries 3.3.4–3.3.6 place upper and dual lower bounds on the same compact-to-ordinary image; the tensor step in 3.2.13 improves an estimate only after additional geometric control. This note supplies a canonical coherent family, its exact source relation ideal on products, and the same-metric reflection/dual operations with which such an upper estimate can now be tested. It does not import finite-field hypotheses into the tau chart.

For an actual eigenvector $A_h v = \rho v$, every constructed tensor metric still has the exact diagnostic

$$\frac{(v^{\otimes k})^* W_{k,M} v^{\otimes k}}{(v^{\otimes k})^* G_{k,M} v^{\otimes k}} = k(2\Re \rho - 1). \quad (10.3)$$

The quantity to bound is therefore the generalized boundary form (8.2) relative to (7.4). A dimension/rank estimate, a decrease of a Gram matrix, or unrestricted metric realizability is not substituted for that relative estimate. The new constructive route is the exact finite full-jet moment problem together with its next-layer flux, not another homotopy choice.

S8.1.12 11. Reading, provenance, and validation

Newly read: both supplied formalization/control notes in full; the preceding local `Tau_Homotopy_Boundary_Control/NOTE.tex`, especially sections 4–10; the retained Deligne English TeX excerpt 3.3.4–3.3.6 and French 6.2.4–6.2.7. This is not a new audit of every page of Weil II. No OCR or PDF extraction was used. Source hashes are in the package reading record.

External context checked: NIST DLMF 5.11.9 for the gamma bound; Connes–Consani–Moscovici, arXiv:2403.01247, abstract, for prior moment/Jacobi constructions from squared absolute local factors; Romik, arXiv:1902.06330, abstract, for prior orthogonal-polynomial expansions of Ξ ; Lasserre–Pauwels, arXiv:1606.03858, abstract, for inverse-moment/Christoffel context. Only the gamma asymptotic is used as an external estimate; the other papers are priority/context references, not sources of an unread theorem. The arguments above prove the specific maps used here.

The accompanying exact checker uses declared finite discrete calibration measures and rational complex polynomial data. It checks the general finite matrix identities, joint relation ranks, signs, full repeated-root reductions, reflection, naturality, and comparison metrics. Its model polynomial is never labelled an arithmetic zeta counterexample. Analytic density, asymptotic gamma bounds, and the original theta range identities are written arguments, not certified by those finite tests. No new Lean execution is claimed. No RH or GRH conclusion is claimed.

S9 Full-jet interpolation kernels and the actual next relation layer

Source attribution. Complete TeX witness from the dated kernel-layer supplement, delivered 12 September 2026. Its handoff identifies PR 14 as the arithmetic source and the existing PR 15 revision as its formal baseline. The supplement’s add-only patch was verified locally; its receipt records no remote branch modification. These NOTE bytes are identified by the source and archive hashes below; neither baseline revision is represented as their Git head.

S9.1 Full-jet interpolation kernels and the actual next relation layer

S9.1.1 Integration supplement — 12 September 2026

This supplement reviews the supplied **Coherent arithmetic interpolation and joint tensor boundary control** package and derives an additional finite-stage bridge. The source’s canonical representative, original theta boundaries, full multiplicities, and support transport are retained. The new formulas below have written proofs and exact finite regression tests; they are **not new Lean certificates**.

The supplied ZIP has SHA-256 a753df8341d05b2fccb6487b1dabc0044153a6c1abcf35092504aadb95c51d26. All 29 entries of its manifest verified. Its note, handoff, and checker match the published Git blobs at PR #14, commit 3bff1b2bd87dfa2592f65c5ccc231f6ee9541dfc. The source checker was independently rerun: nineteen tests passed normally and under optimized Python, with identical result records; the intentionally false twentieth test failed in both modes. See SOURCE_REVIEW_RECEIPT.json.

The comparison with PR #15 is limited precisely: its existing five-module receipt certifies its stated support-changing, relation-layer, finite-Krylov and rank-two interfaces. This supplement does not extend that receipt to the source’s theta analytics, all-degree orthogonal-polynomial construction, or the new tensor-kernel calculations.

S9.1.2 1. Source results retained, rather than reconstructed differently

Write the source polynomial degree as N , to distinguish it from a moment matrix. Fix tensor degree $k \geq 1$, a nonempty packet polynomial h of degree d , and $N \geq k(d-1)$. The packet includes the complete orders of the selected actual zeros. Retain

$$g = 2\xi, \quad E = E_h^{\otimes k}, \quad A = A_h^{(k)}, \quad \mathcal{J}_N : \mathcal{P}_N^{(k)} \twoheadrightarrow E. \quad (1)$$

The last map is reduction modulo the original ideal $(h(t_1), \dots, h(t_k))$, followed by multiplication by the original local unit $v_h^{\otimes k}$. Its kernel is $\mathcal{I}_{k,N}$. The source map is

$$\mathcal{T}(P) = P(D_1, \dots, D_k) F_h^{\otimes k}, \quad \mathcal{MT}(P) = P(s_1, \dots, s_k) \prod_i \frac{g(s_i)}{h(s_i)}. \quad (2)$$

Let $\mathcal{L}_N = \mathcal{TI}_{k,N}$, $P_N = P_{\mathcal{L}_N}$, and let $\sigma : E \hookrightarrow Q^{\widehat{\otimes} k}$ be the source arithmetic inclusion. Its canonical representative and forms are

$$R_N = (I - P_N) s_h^{\otimes k}, \quad G_N = R_N^* R_N \succ 0, \quad q^{(k)} R_N = \sigma, \quad J^{(k)} R_N = I, \quad (3)$$

$$B_N = D^{(k)} R_N - R_N A, \quad W_N = A^* G_N + G_N A - k G_N. \quad (4)$$

The supplied note proves $B_N(E) \subseteq \mathcal{L}_{N+1}$ and, with $\mathcal{E}_N = \mathcal{L}_{N+1} \cap \mathcal{L}_N^\perp$,

$$Y_N = P_{\mathcal{E}_N} R_N, \quad C_N = (I - P_N) B_N, \quad W_N = -(Y_N^* C_N + C_N^* Y_N). \quad (5)$$

These are source results (source note, §§2–4 and 7–9), not claimed as discoveries of this supplement. Their finite-dimensional derivations check: the constrained minimum is over precisely the original ideal, the derivative increases total degree by one, and orthogonal projection removes only the admitted relation space. The source's exact sequence and packet naturality require full orders. Its total-degree statements require the threshold in (1). Its analytic function-space identities remain the stated analytic inputs, not consequences of a finite fixture.

The original coefficient square $G(\mathbb{Z}) \rightarrow G(\mathbb{C})$ over $\mathbb{Z} \rightarrow \mathbb{C}$, with projections $p_{\mathbb{Z}}, p_{\mathbb{C}}$, is unchanged. A vector in an admitted relation maps to the receiving fibre's supported zero, never to external absence τ .

S9.1.3 2. Calculate the inverse interpolation metric by full-jet columns

Use exactly the source measure

$$d\nu_h(t) = \left| \frac{g(1/2 + it)}{h(1/2 + it)} \right|^2 \frac{dt}{2\pi}. \quad (6)$$

Let $p_j^{(h)}(s)$ be its monic orthogonal polynomials, with the polynomial variable evaluated at $s = 1/2 + it$, and retain their positive squared norms

$$\kappa_j^{(h)} = \int |p_j^{(h)}(1/2 + it)|^2 d\nu_h(t) > 0. \quad (7)$$

These are **not** the earlier theta-Krylov vectors u_j , nor their norms $\mathfrak{h}_j$. In particular they depend on h ; they are not assigned norm one. Existence through any finite degree follows from the source measure's positive-definite moment matrices. No limiting assertion is needed here.

Suppress h in notation. For a multi-index α , define

$$p_\alpha = \prod_i p_{\alpha_i}, \quad \kappa_\alpha = \prod_i \kappa_{\alpha_i}, \quad a_j = v_h[p_j]_h \in E_h, \quad a_\alpha = \bigotimes_i a_{\alpha_i} \in E. \quad (8)$$

Every a_j is the full jet, including the local unit. Product orthogonality gives $\langle \mathcal{T} p_\alpha, \mathcal{T} p_\gamma \rangle = \kappa_\alpha \delta_{\alpha\gamma}$. These polynomials form a basis of $\mathcal{P}_N^{(k)}$, because the monic triangular basis change preserves total degree.

Set

$$K_N := G_N^{-1} = \sum_{|\alpha| \leq N} \frac{a_\alpha a_\alpha^*}{\kappa_\alpha}. \quad (9)$$

Proof. In this basis the source moment matrix is $\text{diag}(\kappa_\alpha)$ and the full-jet matrix has columns a_α . Substitute into the source identity $G_N^{-1} = J_N M_N^{-1} J_N^*$. A change of polynomial basis does not change that product. This proves (9) for the same canonical metric, not a newly selected metric.

Its representative has the explicit coefficient formula

$$R_N u = \sum_{|\alpha| \leq N} \mathcal{T}(p_\alpha) \frac{a_\alpha^* G_N u}{\kappa_\alpha}. \quad (10)$$

In particular $R_N K_N$ is an actual map from finite antidual coordinates into the original test-function space. It satisfies $J^{(k)} R_N K_N = K_N$ and $q^{(k)} R_N K_N = \sigma K_N$. The invertible coordinate change K_N is retained, not identified with the identity.

S9.1.4 3. An explicit basis of the original next relation layer

Let $\Sigma_{N+1} = \{\beta \in \mathbb{N}^k : |\beta| = N + 1\}$. Define actual test functions

$$e_\beta = \mathcal{T}(p_\beta) - R_N a_\beta, \quad \beta \in \Sigma_{N+1}. \quad (11)$$

They are in $\mathcal{E}_N$. First, their full jets vanish by (3), so their numerator polynomials lie in the original ideal at degree at most $N + 1$; thus $e_\beta \in \mathcal{L}_{N+1}$. Second, $\mathcal{T}p_\beta$ is orthogonal to all degree-at-most- N polynomials and $R_N a_\beta$ is orthogonal to $\mathcal{L}_N$. Hence $e_\beta \perp \mathcal{L}_N$.

Define

$$\mathcal{E}_N : \mathbb{C}^{\Sigma_{N+1}} \longrightarrow \mathcal{E}_N, \quad c \longmapsto \sum_{\beta} c_\beta e_\beta, \quad (12)$$

$$U_N = (a_\beta)_{\beta \in \Sigma_{N+1}}, \quad D_N = \text{diag}(\kappa_\beta)_{\beta \in \Sigma_{N+1}}. \quad (13)$$

The map $\mathcal{E}_N$ is an isomorphism. Independence follows by taking the degree- $N + 1$ polynomial part of (11). For spanning, subtract from a relation its degree- $N + 1$ combination of the e_β . The remainder is a relation of degree at most N , hence belongs to $\mathcal{L}_N$. An element of $\mathcal{E}_N$ has no such remaining component.

Its Gram matrix and pairing with the representative are exactly

$$H_N := \mathcal{E}_N^* \mathcal{E}_N = D_N + U_N^* G_N U_N, \quad \mathcal{E}_N^* R_N = -U_N^* G_N. \quad (14)$$

The cross terms vanish because the new-degree polynomials are orthogonal to the old polynomial space. In particular $H_N \succ 0$, and no original norm has been suppressed.

This identifies the existing quotient equivalence in coordinates:

$$\mathbb{C}^{\Sigma_{N+1}} \xrightarrow{\mathcal{E}_N} \mathcal{E}_N \xrightarrow{e \mapsto [e]} \mathcal{L}_{N+1} / \mathcal{L}_N. \quad (15)$$

The inverse quotient-to-layer map is the source's $[z] \mapsto (I - P_N)z$. For each nonzero coordinate vector, its class in this relative quotient is nonzero, and its image in the next admitted quotient is zero. At the split level this remains the next supported zero.

For an explicit theta primitive, form $p_\beta - \sum_{|\alpha| \leq N} p_\alpha a_\alpha^* G_N a_\beta / \kappa_\alpha$. Its full jet is zero. Fixed-order monic division expresses it as $\sum_i h(t_i) Q_{i,\beta}$, with $\deg Q_{i,\beta} \leq N + 1 - d$. In the i -th cochain factor use the original ϕ_* in place of F_h , and multiply its primitive by $(-1)^{i-1}$. The differential supplies the same sign, producing the displayed relation with positive sign. This supplies the actual primitive, not just a dimension count.

S9.1.5 4. Both boundary maps now have explicit coordinates

Define the matrix $F_N : E \rightarrow \mathbb{C}^{\Sigma_{N+1}}$ by its rows

$$(F_N)_\beta = \sum_{i: \beta_i > 0} \frac{a_{\beta - \mathbf{e}_i}^*}{\kappa_{\beta - \mathbf{e}_i}}. \quad (16)$$

Then

$$\boxed{Y_N = -\mathcal{E}_N H_N^{-1} U_N^* G_N, \quad C_N = \mathcal{E}_N F_N G_N.} \quad (17)$$

The first equation is the actual orthogonal projection formula using (14). For the second, multiply the finite expansion (10) by $s_1 + \cdots + s_k$. Monicity implies that its degree- $N + 1$ coefficient at p_β is exactly $(F_N)_\beta G_N u$. The term $R_N A u$ has degree at most N . Subtract $\mathcal{E}_N F_N G_N u$ from $B_N u$: the result has degree at most N and zero full jets, hence is in $\mathcal{L}_N$. Projecting by $I - P_N$ proves the equation.

Consequently the old quotient records

$$\boxed{[B_N u]_{\mathcal{B}^{(k)}/\mathcal{L}_N} = [\mathcal{E}_N F_N G_N u]_{\mathcal{B}^{(k)}/\mathcal{L}_N}.} \quad (18)$$

It becomes the supported zero under the next relation transition. The symbol $\mathcal{B}^{(k)}$ denotes the original product test-function space used by the source; no derivative on all of its L^2 completion is defined here.

S9.1.6 5. The control form is a top-degree full-jet endpoint

Define

$$\boxed{V_N := A K_N + K_N A^* - k K_N.} \quad (19)$$

Substituting (17) into the source boundary identity (5), and using $\mathcal{E}_N^* \mathcal{E}_N = H_N$, gives

$$\boxed{W_N = G_N (U_N F_N + F_N^* U_N^*) G_N.} \quad (20)$$

Meanwhile direct multiplication of (4) by K_N on both sides gives $K_N W_N K_N = V_N$. Thus

$$\boxed{V_N = U_N F_N + F_N^* U_N^* = \sum_{|\alpha|=N} \sum_{i=1}^k \frac{a_{\alpha + \mathbf{e}_i} a_\alpha^* + a_\alpha a_{\alpha + \mathbf{e}_i}^*}{\kappa_\alpha}.} \quad (21)$$

This is a finite endpoint identity derived through the actual theta relation layer. It does not assume a small boundary, discard mixed terms, or replace the packet operator. It can also be obtained by finite Christoffel–Darboux telescoping. The standard scalar orthogonal-polynomial kernel and telescoping identities are recorded by NIST (n.d., §18.2(v)); the full-jet, original-layer identification (11)–(21) is proved here rather than imported from that scalar formula.

For this alternative telescoping proof, multiplication satisfies $sp_j = p_{j+1} + \beta_j p_j - (\kappa_j / \kappa_{j-1}) p_{j-1}$, with $\operatorname{Re} \beta_j = 1/2$. The imaginary part need not vanish for the packet-dependent measure. Only $\beta_j + \overline{\beta_j} = 1$ is needed. Interior adjacent terms cancel; (21) is the uncanceled total-degree boundary. The new tests include an asymmetric measure with a nonzero imaginary diagonal coefficient.

Regroup by α and put $b_\alpha = \sum_i a_{\alpha + \mathbf{e}_i}$. Equation (21) factors through the two sets of columns $(a_\alpha)_{|\alpha|=N}$ and $(b_\alpha)_{|\alpha|=N}$. Therefore

$$\boxed{\text{rank } W_N = \text{rank } V_N \leq \min \left\{ d^k, 2 \binom{N+k-1}{k-1} \right\}.} \quad (22)$$

This sharpens the source's general next-layer bound $2 \binom{N+k}{k-1}$ for this product-polynomial construction. It does **not** change the actual dimension of $\mathcal{E}_N$, which remains $\binom{N+k}{k-1}$. The sharpening comes from the scalar summed derivative and regrouping its top-degree columns. For $k = 2, d = 4, N = 6$, the two structural bounds are 14 and 16 on a 16-dimensional packet; the exact regression tests cover this nonvacuous case. Neither rank bound is a small-eigenvalue estimate.

S9.1.7 6. Estimate the same form without a second inversion

Since K_N is Hermitian positive definite,

$$\boxed{-\epsilon G_N \preceq W_N \preceq \epsilon G_N \iff -\epsilon K_N \preceq V_N \preceq \epsilon K_N.} \quad (23)$$

This is congruence by the specified invertible map K_N . More explicitly, for $u = K_N \lambda$, $u^* G_N u = \lambda^* K_N \lambda$ and $u^* W_N u = \lambda^* V_N \lambda$. This identifies the generalized Rayleigh quotients, including multiplicities of generalized eigenvalues. The original generator A is not replaced.

The source's same-metric reflection therefore still transfers an upper estimate to a lower estimate for precisely the original G_N . Under the natural weight- k antidual action $A^D = kI - A^*$, the defect of the antidual metric K_N is $-V_N$, not V_N . The dual sign and weight are both retained.

The reflection map itself can be retained explicitly. If the source involution is $j(u) = C\bar{u}$, its antidual involution is $j^\#(\lambda) = C^T \bar{\lambda}$. From $C\bar{C} = I$ and $C^* G_N C = \overline{G_N}$, inversion gives $(C^T)^* K_N C^T = \overline{K_N}$. The control identity transports to $(C^T)^* V_N C^T = -\overline{V_N}$. Thus the two-sided equivalence retains the actual involution, not only spectral symmetry.

Equation (23) avoids the *second* inversion $G_N = K_N^{-1}$ in the final inequality test. It does not eliminate the need to enclose moments, full-jet coefficients, or the conditioning of the first construction of K_N .

A deterministic finite certificate can therefore work directly with $\hat{K}$, $\hat{A}$ and error bounds $\|K_N - \hat{K}\| \leq \eta_K$, $\|A - \hat{A}\| \leq \eta_A$, where $\hat{K}$ is Hermitian. Put

$$\hat{V} = \hat{A}\hat{K} + \hat{K}\hat{A}^* - k\hat{K}, \quad \eta_V = (2\|\hat{A}\| + k)\eta_K + 2\eta_A(\|\hat{K}\| + \eta_K). \quad (24)$$

Expanding both perturbations proves $\|V_N - \hat{V}\| \leq \eta_V$. Sufficient conditions, for $\epsilon \geq 0$, are

$$\hat{K} - \eta_K I \succ 0, \quad \epsilon \hat{K} \pm \hat{V} - (\epsilon \eta_K + \eta_V) I \succeq 0. \quad (25)$$

No enclosure of the actual infinite arithmetic moments is asserted in this supplement.

S9.1.8 7. The metric update and the univariate connection

The positive update from (9) and its inverse are

$$\boxed{K_{N+1} = K_N + U_N D_N^{-1} U_N^*,} \quad (26)$$

$$\boxed{G_{N+1} = G_N - G_N U_N (D_N + U_N^* G_N U_N)^{-1} U_N^* G_N.} \quad (27)$$

Equation (27) follows either by direct multiplication with (26), or from $R_{N+1} = R_N - Y_N$ and the orthogonal decomposition. The middle matrix is exactly the actual layer Gram matrix H_N in (14), not an unrelated auxiliary matrix. The lost Gram form is $Y_N^* Y_N$.

For $k = 1$ and $N = n + d$, (11) recovers the earlier monic theta vector:

$$\boxed{e_{n+d+1} = u_{n+1}, \quad \mathfrak{h}_{n+1} = \kappa_{n+d+1}^{(h)} + a_{n+d+1}^* G_{h,n} a_{n+d+1}.} \quad (28)$$

Indeed the numerator of (11) is monic of degree $n + d + 1$, divisible by monic h , and its quotient has degree $n + 1$ and leading coefficient one. Applying $\mathcal{T}_h$ gives f_{n+1} plus an element of L_n , orthogonal to L_n . This uniquely identifies u_{n+1} . Thus the packet-dependent polynomial construction is connected to the packet-independent original theta norm by an exact identity; those two norm families were not conflated.

S9.1.9 8. Degree recursion and the remaining estimate

For $A_j = a_j a_j^* / \kappa_j$, define finite matrix sums

$$Q_{k,m} = \sum_{|\alpha|=m} \bigotimes_i A_{\alpha_i}, \quad Q_{k,m} = \sum_{j=0}^m A_j \otimes Q_{k-1,m-j}, \quad K_{k,N} = \sum_{m=0}^N Q_{k,m}. \quad (29)$$

These are finite degree convolutions; they do not assert convergence of an infinite generating series. They compute the product full-jet interpolation matrix using one-variable polynomial norms and jets, without inverting a total-degree moment matrix of dimension $\binom{N+k}{k}$. The target dimension remains d^k ; no polynomial-time complexity or unconditional numerical stability is claimed.

In univariate packet inclusions, the source's exact equality $R_{H,n} \iota_{hH} = R_{h,n}$ remains in force. The packet-dependent polynomial bases used here need not themselves commute under inclusion. No extension of this univariate equality to different joint total-degree budgets is presumed.

Finally, on $Av = k\rho v$, with $v = v_0^{\otimes k}$, and $\lambda = G_N v$,

$$\frac{\lambda^* V_N \lambda}{\lambda^* K_N \lambda} = k(2 \operatorname{Re} \rho - 1). \quad (30)$$

The additional work is therefore the explicit layer basis, derivative-coordinate map, endpoint identity, and direct relative certificate for the same source-controlled object. It is not a proof of a uniform sublinear excess. No arithmetic block or nilpotent jet has been removed.

S9.1.10 Verification and literature scope

The independent new checker contains eighteen exact test methods. They cover the kernel basis change, repeated jets, two-variable layers, actual derivative-class coordinates, Gram updates, the original univariate theta vector, endpoint factorization, a nonvacuous improved rank bound, antidual signs, generalized characteristic polynomials, nonzero off-line *polynomial model* diagnostics, nonreal recurrence diagonals, fixed-order theta primitives, and deterministic matrix perturbation certificates. Normal and optimized result records agree. Both intentional-failure modes return failure.

These are finite regression tests, not proofs of the general analytic inputs and not Lean execution. The general finite identities have the written proofs above. The source's nineteen tests and this supplement's eighteen tests are separate suites, not counts of novel theorems.

The matrix-kernel and Christoffel–Darboux methods have established antecedents. NIST's general orthogonal-polynomial formulas supply the standard scalar comparison. Lasserre and Pauwels (2016) connect inverse moment matrices with orthogonal polynomials and the Christoffel function; only their abstract was examined here, so no theorem from that paper is used as a premise. No global priority claim is made for standard kernel or inverse-update identities.

S10 Arithmetic frontier estimates and symmetric tensor control

Source attribution. Complete TeX witness from the dated symmetric-frontier continuation, delivered 12 September 2026. Its delivery receipt records an add-only local patch based on PR 14, with no remote write. The exact revision below is that patch base; it is not a new remote head for this NOTE. The source and archive hashes identify the complete delivered witness.

Exact revision. 3bff1b2bd87dfa2592f65c5ccc231f6ee9541dfc

Source file. Tau_Symmetric_Frontier_Control/NOTE.tex

This appendix reproduces the complete proof note as a dated source witness. Descriptions of what is new, unavailable, or left for continuation refer to that source revision. The current local continuations and their proofs are in Part I. The appendix is attributed to its originating web contribution; it is not presented as a newly discovered local proof.

Revision scope. Recorded add-only patch base, PR 14

S10.1 Arithmetic frontier estimates and symmetric tensor control

Owner-directed continuation of the split-zero programme, 12 September 2026.

Status. New written deductions from the precise arithmetic source of PR #14, submitted for mathematical review. The supplied Lean receipt certifies its stated coefficient, quotient, homotopy, and topology interfaces; it does not certify the analytic inputs or the results in this note. No purity estimate is assumed. No claim of global novelty is made for the underlying orthogonal-polynomial, finite-group, or matrix identities.

S10.1.1 0. Source and purpose

The source is PR #14 at 3bff1b2bd87dfa2592f65c5ccc231f6ee9541dfc, research-note Git blob 4ec40c15397128552bc276ec903fe59c89657d4e. Its actual total-degree representative, full-jet map, and theta relation ideal are used without changing them.

The source obtained two maps into the next relation layer, with

$$W_{k,M} = -(Y_{k,M}^* C_{k,M} + C_{k,M}^* Y_{k,M}), \quad G_{k,M} - G_{k,M+1} = Y_{k,M}^* Y_{k,M}. \quad (0.1)$$

This note constructs coordinates on that *actual relation layer*, computes the relative control in them, proves a finite arithmetic upper bound, and constructs a smaller symmetric tensor cohomology summand that still contains every repeated eigenline used in amplification. Its exact complement and its trace are retained.

The decisive new coordinate map is

$$b_M(q) = \mathcal{T}_h^{(k)} q - R_{k,M} \mathcal{J} q. \quad (0.2)$$

It converts the highest orthogonal polynomial degree into an original theta boundary and has a calculated inverse and Gram matrix. A highest-degree polynomial alone need not be a boundary; its full-jet value is subtracted by the specific source representative in (0.2).

S10.1.2 1. Unchanged split base, arithmetic source, and quotients

Retain

$$G(R) = \{\tau\} \sqcup \{r^\bullet : r \in R\}, \quad e_R = 0_R^\bullet, \quad \begin{array}{ccc} G(\mathbb{Z}) & \xrightarrow{G(j)} & G(\mathbb{C}) \\ p_{\mathbb{Z}} \downarrow & & \downarrow p_{\mathbb{C}} \\ \mathbb{Z} & \xrightarrow{j} & \mathbb{C}. \end{array} \quad (1.1)$$

The base is the marked absolute point $\mathfrak{b}_\tau$. The first arithmetic target in (1.1) is still infinite. Every fixed-label linear map below is reconstructed by $(\lambda, x) \mapsto (\lambda, Tx)$; its value on external absence is external absence. A vanishing amplitude at an active label remains that label's supported zero.

Use the original $C_+ = [V \xrightarrow{\Theta} \mathcal{B}]$ in degrees 0, 1, where

$$\begin{aligned} V &= \{\phi \in \mathcal{S}(\mathbb{R}) : \phi(-x) = \phi(x), \phi(0) = 0, \int_{\mathbb{R}} \phi = 0\}, \\ \mathcal{B} &= \{F \in C^\infty(\mathbb{R}_{>0}) : \sup_{x>0} x^b |D^j F(x)| < \infty \ (b \in \mathbb{Z}, j \geq 0)\}, \quad D = -x\partial_x, \\ \Theta\phi(x) &= \sum_{n \neq 0} \phi(nx), \quad q : \mathcal{B} \rightarrow Q = \mathcal{B}/\Theta V. \end{aligned}$$

The input is

$$\phi_*(x) = (4\pi^2 x^4 - 6\pi x^2)e^{-\pi x^2}, \quad \mathcal{M}\Theta\phi_*(s) = g(s) = 2\xi(s).$$

Fix a nonempty finite packet of actual nontrivial zeros of g , with their full orders, and define

$$h(t) = \prod_{\rho \in Z} (t - \rho)^{m_\rho}, \quad d = \deg h, \quad E = \mathbb{C}[t]/(h), \quad v_h = g/h, \quad v = j_h v_h \in E^\times. \quad (1.2)$$

No squarefree assumption is made. The source constructs $F_h \in \mathcal{B}$ with $h(D)F_h = \Theta\phi_*$ and $\mathcal{M}F_h = v_h$. It supplies

$$\mathcal{T}_h(P) = P(D)F_h, \quad \mathcal{M}\mathcal{T}_h(P) = v_h P, \quad \mathcal{T}_h(hP) = \Theta(P(D)\phi_*), \quad J_h \mathcal{T}_h(P) = v[P]_h. \quad (1.3)$$

For tensor degree k , put $E_k = E^{\otimes k}$ and $A_k = \sum_{j=1}^k A_j$, where $A = M_t$. Let

$$\begin{aligned} \mathcal{P}_M^{(k)} &= \mathbb{C}[t_1, \dots, t_k]_{\deg \leq M}, \quad M \geq k(d-1), \\ \mathcal{T}^{(k)}P &= P(D_1, \dots, D_k)F_h^{\otimes k}, \quad \mathcal{J}P = v^{\otimes k}[P]_{(h(t_1), \dots, h(t_k))}. \end{aligned} \quad (1.4)$$

The relation space and its realization are

$$\mathcal{I}_M = \mathcal{P}_M^{(k)} \cap (h(t_1), \dots, h(t_k)), \quad \mathcal{B}_M = \mathcal{T}^{(k)}\mathcal{I}_M. \quad (1.5)$$

The source's least-norm representative $R_M : E_k \rightarrow \mathcal{B}^{\otimes k} \subset \mathcal{H}_k$, with $\mathcal{H}_k = L^2(\mathbb{R}_{>0}^k, d^k x)$, satisfies

$$J^{(k)}R_M = 1, \quad q^{\otimes k}R_M = \sigma_h^{\otimes k}, \quad R_M(E_k) \perp \mathcal{B}_M. \quad (1.6)$$

Its finite Gram is $G_M = R_M^* R_M \succ 0$. Every adjoint here is of a finite-domain map into the declared Hilbert observation; no bounded Hilbert-space extension of the full theta map is assumed.

S10.1.3 2. Unscaled polynomial coordinates with every moment retained

The arithmetic measure is exactly

$$d\nu_h(y) = |v_h(\tfrac{1}{2} + iy)|^2 \frac{dy}{2\pi}. \quad (2.1)$$

The source's log-coordinate and Fourier maps give $\|\mathcal{T}_h P\|_{L^2(dx)}^2 = \int |P(\tfrac{1}{2} + iy)|^2 d\nu_h(y)$. The mass of this measure is not set to one.

Starting from $1, t, t^2, \dots$, subtract its orthogonal projections onto the preceding span:

$$p_0 = 1, \quad p_n = t^n - \text{proj}_{\mathcal{P}_{n-1}} t^n, \quad \omega_n = \int |p_n(\tfrac{1}{2} + iy)|^2 d\nu_h(y) > 0. \quad (2.2)$$

No polynomial is divided by its norm. Let T_N be the triangular matrix with columns $p_0, \dots, p_N$ in the original power basis. The exact coordinate relation is

$$T_N^* M_{h,N} T_N = \text{diag}(\omega_0, \dots, \omega_N). \quad (2.3)$$

The earlier seed-boundary vectors $u_n = P_n(D)\Theta\phi_*$ are related to these coordinates by $\mathcal{T}_h(hP_n) = u_n$. Their measure is $|g|^2 dy/(2\pi)$; equation (1.3) is the map to the present $|g/h|^2$ measure. The two orthogonalizations have not been interchanged.

Recurrence. Define $a_0 = 0$ and $a_n = \omega_n/\omega_{n-1}$ for $n \geq 1$. Then

$$tp_n = p_{n+1} + b_n p_n - a_n p_{n-1}, \quad b_n = \frac{\int (\tfrac{1}{2} + iy) |p_n(\tfrac{1}{2} + iy)|^2 d\nu_h(y)}{\omega_n}, \quad \Re b_n = \tfrac{1}{2}. \quad (2.4)$$

Here $p_{-1} = 0$. The possibly nonzero $\Im b_n$ remains. The packet measure need not be even in the height coordinate y .

Proof. Multiplication by t has adjoint multiplication by $1 - t$ for this polynomial inner product. Pairing tp_n with $p_j, j < n-1$, gives zero. Its coefficient of p_{n+1} is one by its leading term; pairing with p_{n-1} gives $-\omega_n/\omega_{n-1}$. The diagonal is the displayed integral. This proves every coefficient. These are the usual orthogonal-polynomial operations, applied through the specified coordinate map rather than changing the arithmetic generator.

For $\alpha \in \mathbb{N}^k$, define

$$p_\alpha = \prod_j p_{\alpha_j}(t_j), \quad \omega_\alpha = \prod_j \omega_{\alpha_j}, \quad z_\alpha = \mathcal{J}p_\alpha \in E_k. \quad (2.5)$$

The columns z_α contain the complete unit $v^{\otimes k}$ and all nilpotent jets.

Inverse-metric formula. In the fixed original basis of E_k ,

$$\mathcal{C}_M = G_M^{-1} = \sum_{|\alpha| \leq M} \frac{z_\alpha z_\alpha^*}{\omega_\alpha}. \quad (2.6)$$

Indeed (2.3) applied to the tensor polynomial basis transforms $JM^{-1}J^*$ exactly into this sum. The representative coefficient on p_α is

$$c_\alpha(u) = \omega_\alpha^{-1} z_\alpha^* G_M u. \quad (2.7)$$

These formulas avoid inversion of a large raw monomial moment matrix, without imposing a new metric.

S10.1.4 3. The highest polynomial degree is isomorphic to the actual new relation layer

Let $\mathcal{U}_M = \text{span}\{p_\beta : |\beta| = M + 1\}$ and retain its ordered basis. Put

$$\Omega = \text{diag}(\omega_\beta)_{|\beta|=M+1}, \quad F = [z_\beta]_{|\beta|=M+1} : \mathbb{C}^r \rightarrow E_k, \quad r = \binom{M+k}{k-1}. \quad (3.1)$$

Write $T_+ : \mathbb{C}^r \rightarrow \mathcal{H}_k$ for the map with columns $\mathcal{T}^{(k)} p_\beta$. Its image is orthogonal to the entire degree- M polynomial image, including $R_M(E_k)$.

The prior actual new relation layer is

$$\mathcal{E}_M = (1 - P_{\mathcal{B}_M})\mathcal{B}_{M+1}.$$

Theorem: relation-graph isomorphism. The map

$$b_M = T_+ - R_M F : \mathbb{C}^r \xrightarrow{\sim} \mathcal{E}_M \quad (3.2)$$

is an isomorphism and has

$$H_M = b_M^* b_M = \Omega + F^* G_M F, \quad b_M^* R_M = -F^* G_M. \quad (3.3)$$

Proof. Its full jet is $F - F = 0$, so (1.5) makes it an actual boundary of degree at most $M + 1$. Both terms are orthogonal to $\mathcal{B}_M$. If $b_M u = 0$, its component in the highest orthogonal polynomial degree is $T_+ u = 0$, so $u = 0$. The source calculation gives $\dim \mathcal{E}_M = r$, proving surjectivity. Alternatively every degree- $M + 1$ boundary has a unique highest orthogonal component; subtract its b_M image and the result lies in $\mathcal{B}_M$. This also constructs the inverse. Orthogonality $T_+^* R_M = 0$ proves (3.3).

A primitive is fully specified: form the numerator $p_\beta - c_M(z_\beta)$, where c_M is (2.7), divide it in the fixed variable order by $h(t_1), \dots, h(t_k)$, and use the original theta primitive in the factor where $h(t_j)$ appears. Give that primitive coefficient $(-1)^{j-1}$; the tensor differential supplies the same sign. No relation is inferred solely from a dimension count.

The comparison with the original internal quotient is

$$\mathbb{C}^r \xrightarrow{b_M} \mathcal{E}_M \xrightarrow{v \mapsto [v]} \mathcal{B}_{M+1}/\mathcal{B}_M \hookrightarrow \mathcal{B}^{\otimes k}/\mathcal{B}_M \longrightarrow \mathcal{B}^{\otimes k}/\mathcal{B}_{M+1}. \quad (3.4)$$

The last composite is zero. Its split lift sends (λ_M, u) to $(\lambda_{M+1}, 0)$, not to τ . At λ_M , $u \neq 0$ represents a nonzero kernel class. The map b_M describes the entire class that is about to become a supported zero.

Representative update. Orthogonal projection onto $b_M(\mathbb{C}^r)$ gives

$$Y_M = -b_M H_M^{-1} F^* G_M, \quad R_{M+1} = R_M + b_M H_M^{-1} F^* G_M. \quad (3.5)$$

Consequently

$$G_{M+1} = G_M - G_M F (\Omega + F^* G_M F)^{-1} F^* G_M, \quad (3.6)$$

$$\mathcal{C}_{M+1} = \mathcal{C}_M + F \Omega^{-1} F^*. \quad (3.7)$$

The complete volume identity is

$$\frac{\det \mathcal{C}_{M+1}}{\det \mathcal{C}_M} = \frac{\det(\Omega + F^* G_M F)}{\det \Omega}. \quad (3.8)$$

The full matrices in (3.6)–(3.7) remain available; their determinant in (3.8) is an additional observation, not their replacement.

S10.1.5 4. Relative control is a highest-degree Christoffel–Darboux identity

For each $|\beta| = M + 1$, put

$$w_\beta = \sum_{j: \beta_j > 0} a_{\beta_j} z_{\beta - e_j}, \quad E_+ = [w_\beta]_{|\beta|=M+1}. \quad (4.1)$$

The name E_+ denotes this finite matrix, not the scalar e or the arithmetic quotient E_h ; its type is $\mathbb{C}^r \rightarrow E_k$.

Theorem: exact displacement.

$$\boxed{Z_M := A_k C_M + C_M A_k^* - k C_M = F \Omega^{-1} E_+^* + E_+ \Omega^{-1} F^*}. \quad (4.2)$$

Proof. Apply (2.4) in each factor of (2.6). A pair of adjacent indices inside $|\alpha| \leq M$ cancels because $a_{\alpha_j+1} = \omega_{\alpha+e_j}/\omega_\alpha$. The diagonal contributes $\sum_j (b_{\alpha_j} + \bar{b}_{\alpha_j}) = k$, precisely the term subtracted in (4.2). The remaining ordered pairs have $|\beta| = M + 1$ and predecessor $\beta - e_j$; collecting them gives (4.1)–(4.2). The imaginary diagonal coefficients cancel with their conjugates here; they were retained in the recurrence and are not assigned zero.

This identity is the tensor total-degree version of the Christoffel–Darboux cancellation. The standard one-variable formula is background; the maps to the full arithmetic quotient and its source boundaries are specified above.

The derivative defect also has an exact expression in the same relation-graph coordinates:

$$B_M = D^{(k)} R_M - R_M A_k, \quad \boxed{C_M^{\text{rel}} := (1 - P_{\mathcal{B}_M}) B_M = b_M \Omega^{-1} E_+^* G_M}. \quad (4.3)$$

Proof. The coefficient of p_β in $D^{(k)} R_M u$ is $\sum_j \omega_{\beta-e_j}^{-1} z_{\beta-e_j}^* G_M u = \omega_\beta^{-1} w_\beta^* G_M u$. The defect is an original boundary. The inverse of (3.2), followed by projection away from $\mathcal{B}_M$, therefore gives (4.3).

Substituting (3.5) and (4.3) into the previous cross-pairing formula proves

$$\boxed{W_M = A_k^* G_M + G_M A_k - k G_M = G_M Z_M G_M = -(Y_M^* C_M^{\text{rel}} + (C_M^{\text{rel}})^* Y_M)}. \quad (4.4)$$

Thus the new highest-degree computation is connected to both maps in the preceding note, including their minus sign and their support-valued boundary primitive.

S10.1.6 4.1 Exact finite certificate and a proved upper estimate

For every real ϵ , congruence by the actual invertible G_M gives

$$\boxed{-\epsilon G_M \preceq W_M \preceq \epsilon G_M \iff -\epsilon C_M \preceq Z_M \preceq \epsilon C_M}. \quad (4.5)$$

This transports the inequality; no eigenvalue or generator has been rescaled.

Put $\mathcal{B} = [F, E_+]$ and

$$J = \begin{pmatrix} 0 & \Omega^{-1} \\ \Omega^{-1} & 0 \end{pmatrix}.$$

The nonzero generalized eigenvalues of (Z_M, C_M) are the nonzero eigenvalues of

$$\boxed{J \mathcal{B}^* G_M \mathcal{B}}. \quad (4.6)$$

The proof is the pair of maps $\mathcal{B} : \mathbb{C}^{2r} \rightarrow E_k$ and $J\mathcal{B}^* G_M : E_k \rightarrow \mathbb{C}^{2r}$ and the equality of nonzero spectra of their two composites. These eigenvalues are real because the first composite is the operator of the Hermitian pencil in (4.5). The $2r$ -matrix itself need not be Hermitian in its displayed coordinates.

There is also a direct upper bound. Let

$$\lambda_{k,M} = \max_{v \neq 0} \frac{v^* F \Omega^{-1} F^* v}{v^* \mathcal{C}_M v},$$

$$\Gamma_{k,M} = \max_{|\alpha|=M} \sum_{j=1}^k (a_{\alpha_j+1} + (k-1)a_{\alpha_j}). \quad (4.7)$$

Then the actual arithmetic control excess satisfies

$$\boxed{\epsilon_{k,M} \leq 2\sqrt{\Gamma_{k,M} \lambda_{k,M}}}. \quad (4.8)$$

Proof. Let Z_M be the columns z_α , $|\alpha| = M$, and $\Omega_M = \text{diag}(\omega_\alpha)$. The lowering-incidence matrix L has $L_{\alpha\beta} = a_{\beta_j}$ when $\alpha = \beta - e_j$, summed over matching j . Then $E_+ = Z_M L$. The matrix $\Omega_M L \Omega^{-1} L^*$ is similar to a positive semidefinite matrix and has nonnegative entries. Its row sum at α is exactly the sum in (4.7), so its spectral radius is at most $\Gamma_{k,M}$. This proves

$$E_+ \Omega^{-1} E_+^* \preceq \Gamma_{k,M} Z_M \Omega_M^{-1} Z_M^* \preceq \Gamma_{k,M} \mathcal{C}_M.$$

Cauchy–Schwarz in the same Ω^{-1} pairing now gives

$$|v^* \mathcal{Z}_M v| \leq 2\sqrt{v^* F \Omega^{-1} F^* v} \sqrt{v^* E_+ \Omega^{-1} E_+^* v} \leq 2\sqrt{\lambda_{k,M} \Gamma_{k,M}} v^* \mathcal{C}_M v.$$

This proves (4.8). The phase-sensitive formula (4.6) is retained for a sharper estimate. Equation (4.8) is not claimed sublinear in k ; its two arithmetic factors are now fully specified.

S10.1.7 5. A symmetric cohomology summand that retains the amplification witnesses

Let $\mathcal{C}_k = C_+^{\widehat{\otimes} k}$ with its original tensor differential. For $\pi \in S_k$, the chain permutation is

$$T_\pi(x_1 \otimes \cdots \otimes x_k) = (-1)^{\sum_{i < j, \pi(i) > \pi(j)} |x_i| |x_j|} x_{\pi^{-1}(1)} \otimes \cdots \otimes x_{\pi^{-1}(k)}. \quad (5.1)$$

The exponent uses the original inputs crossed by π . Adjacent transpositions verify the cochain equation and the permutation relations. In top degree every input has degree one, so $T_\pi = \text{sgn}(\pi) P_\pi$, where P_π is ordinary factor permutation.

Define the actual idempotent

$$\boxed{S_k = \frac{1}{k!} \sum_{\pi \in S_k} \text{sgn}(\pi) T_\pi}. \quad (5.2)$$

The unscaled numerator squares to $k!$ times itself. The displayed $1/k!$ is necessary to make the specified morphism idempotent and is not absorbed into a pairing or an arithmetic function. In degree k the two signs multiply to $+1$, hence

$$\boxed{H^k(S_k \mathcal{C}_k) \cong (Q^{\widehat{\otimes} k})^{S_k}}. \quad (5.3)$$

On a finite packet this contains $(E^{\otimes k})^{S_k}$ with its entire nilpotent action. If $Av = \rho v$, then $v^{\otimes k}$ is nonzero, lies in this summand, and has generator eigenvalue $k\rho$. Using the unsigned chain average instead would give the alternating top-degree summand and would kill a repeated vector for $k > 1$; equation (5.2) is the precise replacement.

The complement is retained through the actual cochain decomposition

$$\mathcal{C}_k \xrightarrow{x \mapsto (S_k x, (1-S_k)x)} \text{im } S_k \oplus \text{im}(1 - S_k), \quad (u, v) \mapsto u + v. \quad (5.4)$$

At an invariant joint support this is reconstructed fibrewise. On all support masks the lift of (5.2) has the specified support map $\lambda \mapsto \bigvee_{\pi} \pi \lambda$. Its formula is the sum of the actual supported scalars $(\text{sgn } \pi / k!) \bullet T_{\pi}$. A vanishing projected amplitude lands at the orbit-joined supported zero, not at τ . Original transports into that joint fibre remain recorded. No injectivity of arbitrary support transports is assumed.

S10.1.8 5.1 The canonical representatives commute with this operation

Permutation of variables preserves the total-degree numerator, its relation ideal, the product arithmetic measure, and the full unit $v^{\otimes k}$. Uniqueness of the constrained minimum gives

$$R_M P_{\pi} = P_{\pi} R_M. \quad (5.5)$$

Consequently R_M restricts to the invariant arithmetic module

$$E_k^{\text{sym}} = (E^{\otimes k})^{S_k}, \quad \boxed{\dim E_k^{\text{sym}} = \binom{k+d-1}{d-1}}. \quad (5.6)$$

This is not a change of the spectral packet. The inclusion $I_k : E_k^{\text{sym}} \hookrightarrow E_k$ gives

$$G_M^{\text{sym}} = I_k^* G_M I_k, \quad W_M^{\text{sym}} = I_k^* W_M I_k, \quad A_k I_k = I_k A_k^{\text{sym}}. \quad (5.7)$$

All repeated eigenlines remain, so this smaller family still contains every witness needed by the tensor-amplification upper estimate. For example, $d = 3, k = 8$ gives dimension 45 rather than $3^8 = 6561$. This is a dimension reduction, not a bound on W_M^{sym} .

S10.1.9 6. Orbit sums give the symmetric matrices with all factorials retained

For a nondecreasing tuple $\lambda \in \mathbb{N}^k$, let $\text{Orb } \lambda$ denote its distinct permutations and

$$n_{\lambda} = \frac{k!}{\prod_{j \geq 0} m_j(\lambda)!}, \quad p_{[\lambda]} = \sum_{\alpha \in \text{Orb } \lambda} p_{\alpha}, \quad \omega_{[\lambda]} = n_{\lambda} \prod_j \omega_{\lambda_j}. \quad (6.1)$$

Distinct product basis vectors are orthogonal, proving the last formula directly. The orbit sum is not divided by its norm or its orbit size.

The target basis is likewise the unscaled orbit sums of $e_{a_1} \otimes \cdots \otimes e_{a_k}$, $0 \leq a_j < d$, where $e_i = [t^i]$. Let I_k be their column inclusion and

$$D_k = I_k^* I_k = \text{diag} \left(\frac{k!}{\prod_i n_i!} \right), \quad L_k = D_k^{-1} I_k^*. \quad (6.2)$$

The explicit L_k extracts the common coefficient on an orbit. For each orbit polynomial, define

$$z_{[\lambda]} = L_k \mathcal{J} p_{[\lambda]}.$$

Then

$$\mathcal{C}_M^{\text{sym}} = \sum_{|\lambda| \leq M} \frac{z^{[\lambda]} z_{[\lambda]}^*}{\omega_{[\lambda]}}, \quad G_M^{\text{sym}} = (\mathcal{C}_M^{\text{sym}})^{-1}. \quad (6.3)$$

The comparison with full coordinates is

$$\mathcal{C}_M^{\text{sym}} = L_k \mathcal{C}_M L_k^*, \quad G_M^{\text{sym}} = I_k^* G_M I_k. \quad (6.4)$$

Inversion and compression have not been commuted without the displayed D_k factors. Equation (6.4) follows because the full form commutes with the orthogonal permutation projection and by substituting $L_k = D_k^{-1} I_k^*$.

The symmetric polynomial numerator has one basis vector per partition of its degree into at most k parts. For $M \geq k(d-1)$ the jet map is onto, because a tensor remainder has total degree at most $k(d-1)$ and averaging makes a symmetric lift of every invariant jet. Thus

$$\dim(\mathcal{E}_M^{S_k}) = p_{\leq k}(M+1), \quad (6.5)$$

where $p_{\leq k}(n)$ is the number of partitions of n into at most k parts. The maps $b_M, Y_M, C_M^{\text{rel}}$ are permutation-equivariant and therefore restrict to that very subspace. Fixed-order polynomial division yields a primitive; applying S_k to it gives a symmetric cochain primitive because $dS_k = S_k d$.

The highest-layer formulas in sections 3–4 hold on the invariant coordinates by grouping F, E_+ into orbit sums, applying L_k , and using the diagonal entries $\omega_{[\lambda]}$. This computes the symmetric bound directly, instead of building a d^k -dimensional matrix first. The upper-bound row-sum estimate can still use the fully retained $\Gamma_{k,M}$; the exact grouped incidence matrix can give a smaller constant.

S10.1.10 6.1 Reflection and the original trace

For a reflection-stable packet the source involution j_h induces $j_h^{\otimes k}$ on both summands in (5.4), commutes with permutations, and preserves the canonical representatives. Hence on the symmetric metric an upper control implies the opposite lower control by the same involution. The residue pairing and its Jacobian map are still transported through their specified inclusions; no auxiliary positive Gram is declared to be the Weil form.

For a finite packet action $U(a) = \exp((\log a)A)$, the exact trace on the invariant summand is

$$\text{Tr}(U(a)^{\otimes k} | E_k^{\text{sym}}) = \frac{1}{k!} \sum_{\pi \in S_k} \prod_{c \in \text{Cycles}(\pi)} \text{Tr}(U(a)^{|c|} | E). \quad (6.6)$$

The proof expands the permutation operator in the tensor basis; each cycle forces the corresponding contracted indices and gives the indicated trace. It holds for nonsemisimple U . The cohomological supertrace is $(-1)^k$ times (6.6). The complement trace remains

$$(-1)^k \left(\text{Tr}(U(a) | E)^k - \text{Tr}(U(a)^{\otimes k} | E_k^{\text{sym}}) \right). \quad (6.7)$$

These are traces of finite-rank cochain projectors on the original complex. An infinite packet sum and its trace topology are not supplied by these formulas.

S10.1.11 7. An exact joint-control calculation with the nilpotent direction retained

This section is a declared algebraic calibration, not a packet of zeta zeros. Take the polynomial quotient

$$E = \mathbb{C}[s]/((s - \frac{1}{2})^2), \quad d\nu(y) = e^{-y^2/2} dy, \quad c = \sqrt{2\pi}.$$

The measure has its literal mass c , and the unit in the calibration jet map is 1. The polynomial basis comparison $x = s - 1/2$ is given by

$$B : \text{span}(1, x) \xrightarrow{\sim} \text{span}(1, s), \quad B = \begin{pmatrix} 1 & -1/2 \\ 0 & 1 \end{pmatrix}. \quad (7.1)$$

The operator remains multiplication by $s = 1/2 + x$. In the symmetric basis

$$1 \otimes 1, \quad 1 \otimes x + x \otimes 1, \quad x \otimes x,$$

its two-fold generator is

$$A_2^{\text{sym}} = \begin{pmatrix} 1 & 0 & 0 \\ 1 & 1 & 0 \\ 0 & 2 & 1 \end{pmatrix}. \quad (7.2)$$

The two-fold total-degree-4 calculation gives

$$\boxed{G_{2,4}^{\text{sym}} = c^2 \text{diag}(1/3, 2/3, 1/4),} \quad (7.3)$$

$$\boxed{W_{2,4}^{\text{sym}} = c^2 \begin{pmatrix} 0 & 2/3 & 0 \\ 2/3 & 0 & 1/2 \\ 0 & 1/2 & 0 \end{pmatrix}.} \quad (7.4)$$

Its generalized characteristic polynomial is

$$\frac{\det(zG_{2,4}^{\text{sym}} - W_{2,4}^{\text{sym}})}{\det G_{2,4}^{\text{sym}}} = z(z^2 - 7/2),$$

so the exact two-sided excess is $\sqrt{7/2}$. The independent rectangular degree-2-per-factor construction gives $\sqrt{6}$ at the same containing total degree. This proves an actual improvement for the specified joint construction in this calibration; the nilpotent operator in (7.2) is unchanged.

For comparison, the smaller joint total degree $M = 2$ has excess $\sqrt{6}$, whereas the rectangular degree-1 construction contained in it has excess 2. Consequently a larger correction space alone does not monotonically improve the control constant. The typed comparison is inclusion of the two polynomial numerators and the resulting Gram compression; the direct formula (4.2) supplies the actual control value. Both calibrations are retained so that the first improvement is not promoted into a false monotonicity theorem.

S10.1.12 8. Exact target, counterfactuals, and handoff

The next estimate is now an arithmetic highest-layer estimate, either by the phase-sensitive pencil (4.5)–(4.6), or by bounding the two factors in (4.8). On the symmetric cohomology family it concerns the same G_M^{sym} and W_M^{sym} , with all relation primitives retained. The source of every matrix entry is the actual measure $|2\xi/h|^2 dy/(2\pi)$, not a fitted metric.

A sublinear excess in tensor degree has not been proved. For every actual eigenvector $Av = \rho v$, the retained witness in the symmetric summand satisfies

$$\frac{(v^{\otimes k})^* W_M(v^{\otimes k})}{(v^{\otimes k})^* G_M(v^{\otimes k})} = k(2\Re\rho - 1). \quad (8.1)$$

The symmetric reduction therefore retains the witness needed by Deligne-style amplification; it does not assume its disappearance. The input Deligne passages use tensoring *and* a separate geometric estimate. Our new work supplies a computable smaller arithmetic target and a proved finite bound, not that geometric estimate by renaming a category.

Constructive continuations are recorded with their exact maps:

- Raw moment inversion: use (2.3)–(2.7), retaining every ω_j and the full jet unit.
- Highest polynomials that are not relations: use $b_M = T_+ - R_M F$, not an assertion that high degree is zero.
- Absolute Gram decay: use the congruence (4.5), retaining $\mathcal{C}_M = G_M^{-1}$ and the whole highest-layer update.
- Excessive tensor dimension: use the chain projector (5.2) and the symmetric numerator/quotient (6.1)–(6.5), while retaining the complementary cohomology and trace.
- A Cauchy–Schwarz bound too large: use the exact signed matrix (4.6); its phases and cross terms have not been replaced by their absolute values in the stored data.
- Ordinary zero observations: reconstruct the maps and kernels in (3.4). A new relation is *e*-zero at the next label; the original class and the full kernel remain upstream.

The supplied quotient/homotopy Lean results can formalize the finite algebra of (3.2)–(4.6) and the chain-permutation calculation. The original analytic range theorem, arithmetic moment bounds, and any uniform tensor estimate remain separate written-analysis inputs.

S10.1.13 References and evidence scope

The current input was read in the mounted NOTE.tex and checked against the pinned public mark-down (especially sections 7–9). The prior formalization receipt was read at its recorded scope: its section-change and internal-quotient statements are used, without treating its analytic assumptions as proved Lean theorems.

The classical orthogonal-polynomial recurrence and Christoffel–Darboux formula are documented in NIST DLMF sections 18.2(iv)–(v), <https://dlmf.nist.gov/18.2>. The tensor complex and its signed commutativity are documented in the Stacks Project, Tag 0GWN, <https://stacks.math.columbia.edu/tag/0GWN>. These are background mechanisms; sections 3–6 above prove their specific maps on this arithmetic source.

The retained Deligne reading for the intended amplification is the supplied account of Weil II 3.2.13 and 3.3.4–3.3.6. No new full rereading of Weil II is claimed in this turn. No external source corpus is redistributed in this package.

The checker uses exact finite Gaussian moment fixtures, including repeated-root quotients, non-constant units, a nonzero imaginary recurrence diagonal, and both signed chain degrees. They are not arithmetic measurements. All derived infinite-dimensional statements rest on the written arguments and the explicitly named prior analytic inputs, not on the finite tests.

S11 Complete spectral-sum descent: relative arithmetic fibres, dual resolution and all nilpotents

Source attribution. Complete spectral-sum TeX witness retained inside the sum-connection delivery archive. The earlier public PR 17 Markdown note is separately preserved in this reader. This longer witness includes the original sum-action resolution, linear dual and antidual comparison, Ext and resolvent calculations, full matrix weight and constrained minimum. The associated public revision below is not a Git identity assigned to these longer TeX bytes; the source and archive hashes identify them.

S11.1 Spectral-sum descent with the relative arithmetic fibre retained

Owner-directed continuation of the split-zero programme. 12 September 2026.

Status. Written deductions for review. These results use the actual theta range and representative constructions stated in the preceding packages. Their analytic inputs are not newly Lean-certified. The finite polynomial, quotient, and matrix statements below have independent proofs and executable finite tests. No RH, GRH, or sublinear arithmetic weight bound is asserted.

S11.1.1 1. Integration and purpose

The new Kernel-Layer Integration supplement and the preceding Symmetric Frontier note overlap in their explicit relation basis and inverse-metric control. We retain the dictionary

$$K_N = \mathcal{C}_M, \quad U_N = F, \quad D_N = \Omega, \quad \mathcal{E}_N = b_M, \quad F_N = \Omega^{-1}E_+^*, \quad V_N = \mathcal{Z}_M, \quad N = M. \quad (1.1)$$

The supplement's sharper rank bound follows by grouping the summed derivative at degree M rather than counting all degree- $M+1$ coordinates. Its identities are not counted again as new work. In particular its one-variable map

$$e_{n+d+1} = u_{n+1}, \quad \mathfrak{h}_{n+1} = \kappa_{n+d+1}^{(h)} + a_{n+d+1}^* G_{h,n} a_{n+d+1} \quad (1.2)$$

is retained: it identifies the packet-dependent interpolation layer with the original packet-independent theta relation by an actual polynomial-divisibility map.

The new step is to push the arithmetic tensor system along its **sum coordinate**, retaining the relative coordinates in a matrix-valued arithmetic measure. We calculate the entire symmetric-square relation algebra, its original theta primitives, the exact norm under the pushforward, and the full

nilpotent fibres of the sum action. This is a product-to-one-parameter construction on the existing characteristic-zero object over the tau base. It is not a use of finite-field purity with relabelled coefficients.

S11.1.2 2. Unchanged source, split quotient, and tensor cohomology

Keep

$$G(R) = \{\tau\} \sqcup \{r^\bullet : r \in R\}, \quad e_R = 0_R^\bullet, \quad \begin{array}{ccc} G(\mathbb{Z}) & \xrightarrow{G(j)} & G(\mathbb{C}) \\ p_{\mathbb{Z}} \downarrow & & \downarrow p_{\mathbb{C}} \\ \mathbb{Z} & \xrightarrow{j} & \mathbb{C}. \end{array} \quad (2.1)$$

The first quotient remains infinite. All spaces and morphisms are marked over the existing absolute pointed base $\mathfrak{b}_\tau$. At an active coefficient label λ , the lift of a linear map T is $(\lambda, x) \mapsto (\lambda, Tx)$; it fixes external absence. Its amplitude-zero value is $(\lambda, 0)$, the image of the original supported-zero action, not τ .

Use precisely

$$V = \{\phi \in \mathcal{S}(\mathbb{R}) : \phi \text{ even}, \phi(0) = 0, \int_{\mathbb{R}} \phi = 0\}, \quad \mathcal{B} = \{F : \sup_{x>0} x^b |D^j F(x)| < \infty (b \in \mathbb{Z}, j \geq 0)\}, \quad D = -x\partial_x, \\ C_+ = [V \xrightarrow{\Theta} \mathcal{B}], \quad \Theta\phi(x) = \sum_{n \neq 0} \phi(nx), \quad Q = \mathcal{B}/\Theta V, \\ \phi_* = (4\pi^2 x^4 - 6\pi x^2)e^{-\pi x^2}, \quad \mathcal{M}\Theta\phi_* = g, \quad g(s) = 2\xi(s). \quad (2.2)$$

For a finite nonempty packet of actual zeros with their full orders, put

$$h(s) = \prod_{\rho \in Z} (s - \rho)^{m_\rho}, \quad d = \deg h, \quad E_h = \mathbb{C}[s]/(h), \quad v_h = g/h, \quad v_h = j_h v_h \in E_h^\times.$$

The prior analytic construction supplies $F_h \in \mathcal{B}$ with $\mathcal{M}F_h = v_h$ and $h(D)F_h = \Theta\phi_*$. Retain its maps

$$\mathcal{T}_h(P) = P(D)F_h, \quad \mathcal{T}_h(hP) = \Theta(P(D)\phi_*), \quad J_h \mathcal{T}_h(P) = v_h[P]_h. \quad (2.3)$$

For tensor degree k , use $\mathcal{P}_M = \mathbb{C}[s_1, \dots, s_k]_{\deg \leq M}$ and

$$E_k = E_h^{\otimes k}, \quad A_k = M_{s_1 + \dots + s_k}, \quad \mathcal{T}_k(P) = P(D_1, \dots, D_k)F_h^{\otimes k}, \\ I_{k,M} = \mathcal{P}_M \cap (h(s_1), \dots, h(s_k)), \quad B_{k,M} = \mathcal{T}_k I_{k,M}. \quad (2.4)$$

The jet map $\mathcal{J}_k P = v_h^{\otimes k}[P]$ has this exact kernel and is onto when $M \geq k(d-1)$. This map is linear, with an invertible unit multiplication after the algebra quotient; it is not called a unital algebra homomorphism. The source representative $R_{k,M}$ is its unique least-norm lift with the specified theta relations allowed. Thus

$$J^{(k)} R_{k,M} = 1, \quad q^{(k)} R_{k,M} = \sigma_h^{\otimes k}, \quad G_{k,M} = R_{k,M}^* R_{k,M}, \quad W_{k,M} = A_k^* G_{k,M} + G_{k,M} A_k - k G_{k,M}. \quad (2.5)$$

The tensor differential retains $(-1)^{j-1}$ when it applies the differential in the j th factor to a degree- $(k-1)$ primitive with all other factors of degree one. A primitive for the positive relation $h(s_j)P_j$ has the matching sign $(-1)^{j-1}$.

In top degree the signed chain projector

$$S_k = \frac{1}{k!} \sum_{\pi \in S_k} \text{sgn}(\pi) T_\pi \quad (2.6)$$

selects ordinary symmetric tensors: the Koszul sign in T_π supplies the second permutation sign. The factor $1/k!$ is retained. We work on this image while retaining the complementary chain projector $1 - S_k$ and its trace. A source mask is transported to the union of its permutation orbit before averaging; its cancelled coordinates remain supported at that joined label.

S11.1.3 3. The spectral-sum direct image is an exact functor with its action fixed

Define the actual ring map

$$\iota_k : \mathbb{C}[S] \longrightarrow E_k, \quad S \longmapsto [s_1 + \cdots + s_k]. \quad (3.1)$$

For an E_k -module M , let $\pi_{k*}M$ be that same module with the $\mathbb{C}[S]$ action restricted through ι_k . The functor is exact because its maps, kernels, and underlying abelian groups are unchanged. It has the explicit adjunction

$$\text{Hom}_{E_k}(E_k \otimes_{\mathbb{C}[S]} L, M) \cong \text{Hom}_{\mathbb{C}[S]}(L, \pi_{k*}M), \quad (3.2)$$

with forward map $f \mapsto (l \mapsto f(1 \otimes l))$ and inverse $a \otimes l \mapsto af(l)$. On quasi-coherent sheaves this is pushforward along the finite morphism $\text{Spec } E_k \rightarrow \text{Spec } \mathbb{C}[S]$. The affine pushforward statement concerns quasi-coherent complexes, not all sheaves of modules (Stacks, Tag 0AVV).

The split map is $G(\iota_k)$, with

$$p_{E_k} G(\iota_k) = \iota_k p_{\mathbb{C}[S]}, \quad G(\iota_k)(e_{\mathbb{C}[S]}) = e_{E_k}, \quad G(\iota_k)(\tau) = \tau. \quad (3.3)$$

Consequently the geometric arrow is over the same $\mathfrak{b}_\tau$. It does not replace that base by a finite field. The additional line $\text{Spec } \mathbb{C}[S]$ is the recipient of a specified arithmetic correspondence.

At the original cochain level, S acts by $D_1 + \cdots + D_k$. Its finite representative equation remains

$$D^{(k)} R_{k,M} - R_{k,M} A_k = dK_{k,M} \in B_{k,M+1}. \quad (3.4)$$

The jet and cohomology maps intertwine that action exactly. Restriction of scalars preserves their kernels and this boundary equation. It does not declare the chosen representative $R_{k,M}$ equivariant.

On the symmetric summand the ring is $B_k = (E_k)^{S_k}$, its inclusion is the original invariant inclusion, and S acts by the same sum. Exactness of taking invariants here follows from the specified Reynolds projector $k!^{-1} \sum P_\pi$ over $\mathbb{C}$.

S11.1.4 3.1 The pushforward has a computed free resolution and dualizing comparison

Let E denote the actual finite ordered or symmetric image, with its exact sum operator A . Put $R = \mathbb{C}[S]$ and $n = \dim_{\mathbb{C}} E$. There is the actual free resolution

$$0 \longrightarrow R \otimes_{\mathbb{C}} E \xrightarrow{SI-A} R \otimes_{\mathbb{C}} E \xrightarrow{\text{ev}_A} \pi_* E \longrightarrow 0, \quad \text{ev}_A(P \otimes v) = P(A)v. \quad (3.5)$$

Injectivity of $SI - A$ follows either from its monic nonzero determinant or by inspecting the highest coefficient of a polynomial vector. To identify the kernel of ev_A , use

$$S^j v - A^j v = (SI - A) \sum_{i=0}^{j-1} S^{j-1-i} A^i v.$$

Subtracting these displayed relations leaves precisely the constant vector $\text{ev}_A(f)$. This proves exactness with both original arrows retained.

Let $E^\vee = \text{Hom}_{\mathbb{C}}(E, \mathbb{C})$ and $A^\vee \lambda = \lambda \circ A$. This is the algebraic dual; its matrix is a transpose. The coefficient conjugation $\overline{E^\vee} \rightarrow E^\#$, $\bar{\lambda} \mapsto (v \mapsto \overline{\lambda(v)})$, connects it explicitly to the antidual used in the control matrices.

Applying $\text{Hom}_R(-, R dS)$ to (3.5) gives

$$R \text{Hom}_R(\pi_* E, R dS) \simeq [R \otimes E^\vee dS \xrightarrow{SI - A^\vee} R \otimes E^\vee dS], \quad (3.6)$$

in degrees 0, 1. Its degree-zero group is zero, and

$$\boxed{\text{Ext}_R^1(\pi_* E, R dS) \cong E^\vee, \quad [P(S) dS] \mapsto P(A^\vee).} \quad (3.7)$$

Here $P(A^\vee)$ means $\sum_j (A^\vee)^j \lambda_j$ for a polynomial dual vector $P(S) = \sum_j S^j \lambda_j$. The inverse is the constant class $\lambda \mapsto [\lambda dS]$.

For the explicit cohomological shift, $C[b]^i = C^{i+b}$. Thus

$$R \text{Hom}_R(\pi_* E[-k], R dS[1]) \simeq E^\vee[k]. \quad (3.8)$$

The degree- k arithmetic image becomes degree $-k$ under the stated dualizing object of the sum line. These shifts are obtained from (3.6), not inferred by calling the finite packet a curve.

The adjoint behind this calculation is the actual module-category map

$$\text{Hom}_R(\pi_* M, L) \cong \text{Hom}_{B_k}(M, \text{Hom}_R(B_k, L)), \quad f \mapsto (m \mapsto (b \mapsto f(bm))). \quad (3.9)$$

The inverse evaluates the inner map at 1. Passing to derived Hom gives the corresponding derived right adjoint. This concerns the exact restriction functor on module categories; no exactness of pushforward on all sheaves is asserted (Stacks, Tag 0AWZ).

S11.1.5 3.2 Resolve the finite arithmetic trace through that same duality

The pairing in (3.7) is equivalently the concrete resolvent-residue pairing

$$\boxed{\langle v, [P(S) dS] \rangle = \sum_{\lambda \in \text{Spec } A} \text{Res}_{S=\lambda} P(S) ((SI - A)^{-1} v) dS.} \quad (3.10)$$

Relations from $SI - A^\vee$ produce polynomial expressions with no finite residue. Expanding the resolvent at infinity proves that the sum is $P(A^\vee)(v)$: the coefficient of S^{-1} is $\sum_j \lambda_j (A^j v)$. This proves perfectness without deleting nilpotents.

On a block $A = \lambda I + N$ the retained resolvent is

$$(SI - A)^{-1} = \sum_{j=0}^{\ell-1} \frac{N^j}{(S - \lambda)^{j+1}}, \quad N^\ell = 0. \quad (3.11)$$

The trace observation of that resolvent is a further specified map. For a function ψ holomorphic at the finite spectrum,

$$\boxed{\mathrm{Tr}(\psi(A)) = \sum_{\lambda} \mathrm{Res}_{S=\lambda} \psi(S) \mathrm{Tr}((SI - A)^{-1}) dS = \sum_{\lambda} \mathrm{Res}_{S=\lambda} \psi(S) \frac{\chi'_A(S)}{\chi_A(S)} dS,} \quad (3.12)$$

where $\chi_A(S) = \det(SI - A)$ is the exact finite characteristic polynomial. It is not substituted for the original $g = 2\xi$. With $\psi(S) = a^S$, (3.12) is the finite Lefschetz contribution of the same diagonal scaling correspondence. The cochain image is in degree k , so its supertrace includes $(-1)^k$.

The constant-class maps in (3.5)–(3.7), and the linear functional in (3.10), lift fibrewise to the original split objects. Every zero functional or zero residue remains supported. At fixed label the equations forming the resolution have composite the supported zero map. The residue pairing is an ordinary bilinear pairing in that coefficient fibre, with its split lift separately additive, not a linear map on its Cartesian product.

S11.1.6 4. The symmetric tensor-square has an explicit two-generator relation algebra

Use three distinguished polynomials

$$S = s_1 + s_2, \quad r = s_1 - s_2, \quad \Delta = r^2. \quad (4.1)$$

The inverse map before taking invariants is

$$s_1 = (S + r)/2, \quad s_2 = (S - r)/2.$$

Swap fixes S and sends r to $-r$. Therefore the algebra map

$$\Phi : \mathbb{C}[S, \Delta] \xrightarrow{\sim} \mathbb{C}[s_1, s_2]^{S_2}, \quad S \mapsto s_1 + s_2, \quad \Delta \mapsto (s_1 - s_2)^2 \quad (4.2)$$

is an isomorphism. Its proof is even/odd expansion in r , using the displayed inverse with both factors $1/2$. Give S degree one and Δ degree two; then Φ preserves the entire original total-degree filtration.

Define actual polynomials H_0, H_1 by

$$\begin{aligned} h((S + r)/2) &= H_0(S, r^2) + rH_1(S, r^2), \\ h((S - r)/2) &= H_0(S, r^2) - rH_1(S, r^2). \end{aligned} \quad (4.3)$$

In particular H_0 is the half-sum and H_1 is the difference divided by $2r$. That difference is an odd polynomial, so this is polynomial division, not localization away from $r = 0$.

Theorem (complete symmetric relation ideal).

$$\boxed{B_2 = (E_h \otimes E_h)^{S_2} \cong \mathbb{C}[S, \Delta]/(H_0, \Delta H_1).} \quad (4.4)$$

Proof. In $\mathbb{C}[S, r]$, the original ideal $(h(s_1), h(s_2))$ is (H_0, rH_1) . Its even part is exactly (H_0, r^2H_1) : average an expression $H_0a + rH_1b$ under $r \mapsto -r$. Writing $a = a_0 + ra_1$, $b = b_0 + rb_1$ gives the even expression $H_0a_0 + \Delta H_1b_1$. Conversely both generators are in the original ideal. Invariants of the quotient equal the quotient of invariants because Reynolds averaging is an exact projector. This proves (4.4), including coincident roots and all nilpotents.

The quotient has dimension $d(d+1)/2$. Indeed the unscaled orbit sums of the basis $s_1^i s_2^j$, $0 \leq i, j < d$, give that many independent invariant vectors. The associated graded Hilbert series is

$$\sum_{0 \leq i \leq j < d} z^{i+j} = \frac{(1-z^d)(1-z^{d+1})}{(1-z)(1-z^2)}. \quad (4.5)$$

Here associated graded refers to the original degree filtration; (4.5) is not a claim that a nonhomogeneous h defines a graded algebra. Polynomial remainder lowers degree, and Reynolds averaging respects the filtration, proving the formula for every monic h of degree d .

S11.1.7 4.1 All original primitives and their degrees survive

Let a symmetric relation of degree at most M have, after original ordered division, the expression $h(s_1)Q_1 + h(s_2)Q_2$ with $\deg Q_i \leq M-d$. Averaging yields paired coefficients

$$C_1 = (Q_1 + Q_2 \circ \text{swap})/2, \quad C_2 = C_1 \circ \text{swap}.$$

Put $A_0 = C_1 + C_2$ and $A_1 = (C_1 - C_2)/r$. Then A_0, A_1 are polynomials in S, Δ and

$$H_0 A_0 + \Delta H_1 A_1 = h(s_1) \frac{A_0 + r A_1}{2} + h(s_2) \frac{A_0 - r A_1}{2}. \quad (4.6)$$

Their weighted degree bounds are $\deg A_0 \leq M-d$ and $\deg A_1 \leq M-d-1$. The two source primitives are respectively

$$\frac{A_0 + r A_1}{2} (D_1, D_2) (\phi_* \otimes F_h), \quad -\frac{A_0 - r A_1}{2} (D_1, D_2) (F_h \otimes \phi_*). \quad (4.7)$$

The negative sign in the second primitive meets the negative cochain sign of the second differential. Applying d gives exactly (4.6) through $\mathcal{T}_2$.

The unit $v_h \otimes v_h$ is symmetric. Under (4.4) denote its full class by $v_{2,h}$. The jet map in these coordinates is exactly

$$\mathcal{J}'_{2,M} : \mathbb{C}[S, \Delta]_{\deg S + 2 \deg \Delta \leq M} \longrightarrow B_2, \quad P \longmapsto v_{2,h}[P]. \quad (4.8)$$

Its kernel is the full weighted-degree part of $(H_0, \Delta H_1)$. It is onto for $M \geq 2(d-1)$. This is the original full-jet map conjugated by Φ , not a scalar evaluation at the sum coordinate.

On the split totals, $\tilde{\Phi}(\lambda_M, P) = (\lambda_M, \Phi P)$ and $\tilde{\Phi}(\tau) = \tau$. The induced isomorphism of relation quotients commutes with every $M \rightarrow M+1$. A nonzero new relation therefore becomes $(\lambda_{M+1}, 0)$ under exactly the same degree transition as before.

S11.1.8 5. The arithmetic norm becomes a one-variable matrix weight

Let

$$w_h(t) = \left| \frac{g(1/2 + it)}{h(1/2 + it)} \right|^2 \frac{1}{2\pi}, \quad d\nu_h(t) = w_h(t) dt. \quad (5.1)$$

No mass is assigned the value one. The source norm of a two-variable polynomial is

$$\|\mathcal{T}_2 P\|^2 = \int_{\mathbb{R}^2} |P(1/2 + it_1, 1/2 + it_2)|^2 w_h(t_1) w_h(t_2) dt_1 dt_2.$$

Make the exact real coordinate change

$$u = t_1 + t_2, \quad v = t_1 - t_2, \quad (t_1, t_2) = ((u+v)/2, (u-v)/2), \quad dt_1 dt_2 = \frac{1}{2} du dv. \quad (5.2)$$

Then $S = 1 + iu$, $r = iv$, and $\Delta = -v^2$. If

$$P(S, \Delta) = \sum_{a=0}^b \Delta^a f_a(S), \quad b = \lfloor M/2 \rfloor, \quad \deg f_a \leq M - 2a,$$

define the full matrix

$$W_{h,b}(u)_{ac} = \frac{(-1)^{a+c}}{2} \int_{\mathbb{R}} v^{2(a+c)} w_h((u+v)/2) w_h((u-v)/2) dv. \quad (5.3)$$

Theorem (isometric spectral-sum realization).

$$\|\mathcal{T}_2 \Phi P\|^2 = \int_{\mathbb{R}} f(1 + iu)^* W_{h,b}(u) f(1 + iu) du. \quad (5.4)$$

This follows by (5.2), finite polynomial expansion, and Fubini. All integrals converge by the source's exponential moments. For every real u , the matrix $W_{h,b}(u)$ is positive definite: its quadratic form is the integral of the squared modulus of a nonzero polynomial in $-v^2$ against a density positive almost everywhere. Zeros of the nonzero entire g/h are discrete and cannot remove a positive-measure set of the v -line. The exponential bounds prove convergence also for each fixed u .

For $b = 0$ the scalar coefficient is the convolution

$$W_{h,0}(u) = (w_h * w_h)(u). \quad (5.5)$$

For $b > 0$, its additional rows are the actual relative-coordinate moments. They have not been replaced by (5.5).

The map in (5.4) sends a polynomial to its vector of coefficient functions; its inverse is $f \mapsto \sum \Delta^a f_a(S)$ on the specified filtered image. Multiplication by $s_1 + s_2$ is exactly multiplication by S on every component. Hence its generator is still A_2 , its degree increase is still one, and its boundary is still (3.4).

S11.1.9 5.1 General tensor degree

For any k , set $S = \sum s_i$, retain $x_i = s_i$ for $i < k$, and put $s_k = S - \sum_{i < k} x_i$. This is a polynomial algebra isomorphism with determinant one on the real variables $(t_1, \dots, t_k) \leftrightarrow (t_1, \dots, t_{k-1}, u = \sum t_i)$.

Write $P = \sum_{\alpha} x^{\alpha} f_{\alpha}(S)$, with $\deg f_{\alpha} \leq M - |\alpha|$. Its matrix weight is

$$W_{k,M}(u)_{\alpha\beta} = \int_{\mathbb{R}^{k-1}} \prod_{i < k} \overline{(1/2 + it_i)^{\alpha_i}} \prod_{i < k} (1/2 + it_i)^{\beta_i} \prod_{i < k} w_h(t_i) w_h(u - \sum_{i < k} t_i) d^{k-1}t. \quad (5.6)$$

The outer coordinate is $S = k/2 + iu$. The same proof gives an isometry on the actual degree- M source, with every original relation substituted through this algebra isomorphism. Its entries have exponential moments in u for every exponent below the source threshold $\pi/2$: use $|\sum t_i| \leq \sum |t_i|$, the polynomial factors, and the one-variable exponential moment. Constants depend on the retained packet, k , and degrees; no uniform-in- k estimate is inferred.

S11.1.10 6. The canonical representative, kernel control and relation layers commute with the descent

Let C_M be the explicit coefficient matrix of Φ from $S^a \Delta^b$ to the original symmetric polynomial basis. It is invertible between those two filtered spaces. Let U be the exact coordinate map of (4.4) to the original unscaled invariant quotient basis. Retain its orbit coefficients.

For the source moment and full-jet matrices,

$$M'_M = C_M^* M_M C_M, \quad J'_M = U^{-1} J_M C_M. \quad (6.1)$$

The matrix in (5.3) gives exactly M'_M by one-dimensional integration of its entries against the retained powers of S .

The inverse interpolation kernel and its metric satisfy

$$K'_M = J'_M (M'_M)^{-1} (J'_M)^* = U^{-1} K_M (U^{-1})^*, \quad G'_M = U^* G_M U. \quad (6.2)$$

These identities follow by multiplying the stated inverses, not by selecting a new metric. The least-norm representatives obey $R'_M = R_M U$ after their polynomial-source identification. Their action and control are

$$A'_2 = U^{-1} A_2 U, \quad W'_M = U^* W_M U, \quad \mathcal{Z}'_M = U^{-1} \mathcal{Z}_M (U^{-1})^*. \quad (6.3)$$

Thus every control inequality is exactly transported. The same isometry sends the actual next boundary layer, its Gram matrix, and its two maps Y_M, C_M^{rel} to their images in (5.4). It preserves the finer rank bound supplied by the new attachment.

The arithmetic representative defect remains a relation with an explicit primitive (4.7). Its cross-pairing is evaluated by (5.3); it is not erased when the relation becomes a supported zero in the next internal quotient.

S11.1.11 6.1 Retain the base and relative parts of the norm separately through a triangular map

Write the finite matrix weight as

$$W(u) = \begin{pmatrix} m_0(u) & b(u) \\ b(u)^* & C(u) \end{pmatrix}, \quad m_0(u) > 0.$$

There is the exact isometric map into the stated direct-sum weighted space

$$\mathcal{A} : f \mapsto (f_0 + m_0^{-1} b f_{\text{rel}}, f_{\text{rel}}), \quad (6.4)$$

with inverse $(a, z) \mapsto (a - m_0^{-1} b z, z)$ and weights

$$m_0(u), \quad C(u) - b(u)^* m_0(u)^{-1} b(u). \quad (6.5)$$

Completing the square proves the isometry and positivity of the second weight. No measure is renormalized: m_0 and its reciprocal are both in the formulas. The image $\mathcal{A}(\mathcal{P}_M^{\text{sym}})$ is retained, not enlarged to arbitrary functions in the target. The ratio $m_0^{-1} b$ need not be polynomial. Multiplication by $S = 1 + iu$ commutes with this pointwise map, so the derivative action is still specified without a new connection term.

This supplies two concrete analytic quantities for the next estimates: the convolution mass and the full relative covariance matrix. Neither positivity of this representative norm nor the scalar mass alone is being substituted for the arithmetic Weil pairing.

S11.1.12 7. Calculate every nilpotent fibre of the sum map

The pushforward must not replace a multiple jet by its residue. We now give its complete Jordan lengths.

For an ordered root tuple $(\rho_1, \dots, \rho_k)$ with retained orders m_i , its local algebra is

$$L_\rho = \mathbb{C}[z_1, \dots, z_k]/(z_1^{m_1}, \dots, z_k^{m_k}), \quad A_k = \rho_\Sigma I + N, \quad \rho_\Sigma = \sum \rho_i, \quad N = M_{\sum z_i}. \quad (7.1)$$

Let $D_0 = \sum (m_i - 1)$ and $c_r = [t^r] \prod_i (1 + t + \dots + t^{m_i-1})$, with $c_{-1} = 0$.

Theorem (full ordered sum-fibre decomposition). As a $\mathbb{C}[S]$ -module,

$$\pi_{k*} L_\rho \cong \bigoplus_{r=0}^{\lfloor D_0/2 \rfloor} (\mathbb{C}[S]/(S - \rho_\Sigma)^{D_0-2r+1})^{\oplus (c_r - c_{r-1})}. \quad (7.2)$$

Here the isomorphism is constructed by primitive vectors, as follows. On z_i^j set

$$F_i z_i^j = j(m_i - j) z_i^{j-1}, \quad H_i z_i^j = (2j - (m_i - 1)) z_i^j.$$

For $F = \sum F_i$ and $H = \sum H_i$, direct substitution gives

$$[N, F] = H, \quad [H, N] = 2N, \quad [H, F] = -2F. \quad (7.3)$$

An auxiliary positive inner product making $F = N^*$ is explicitly diagonal:

$$\langle z^\alpha, z^\beta \rangle_0 = \delta_{\alpha\beta} \prod_i \frac{\alpha_i! (m_i - 1)!}{(m_i - 1 - \alpha_i)!}. \quad (7.4)$$

These are specified positive numbers. For the actual arithmetic Gram $G_{k,M}$ and the displayed diagonal Gram G_0 , their exact comparison is the invertible operator $C_0 = G_{k,M}^{-1} G_0$, with inverse $G_0^{-1} G_{k,M}$:

$$\langle v, w \rangle_0 = \langle v, C_0 w \rangle_{G_{k,M}}. \quad (7.4a)$$

Equation (7.4) is used only to prove the algebraic decomposition. All arithmetic control remains with $G_{k,M}$. In the primitive-ladder basis its entries are $(N^i p)^* G_{k,M} (N^j q)$, including all cross-ladder terms. They are not discarded because the auxiliary Gram admits orthogonal ladders.

A primitive vector p has degree r and satisfies $Fp = 0$. Put $w = D_0 - 2r$. The commutators prove

$$FN^j p = j(w - j + 1) N^{j-1} p, \quad \|N^j p\|_0^2 = \frac{j! w!}{(w - j)!} \|p\|_0^2 \quad (0 \leq j \leq w). \quad (7.5)$$

Thus its ladder has length $w + 1$ and $N^{w+1} p = 0$. Conversely a nonzero lowest vector has $r \leq D_0/2$, since $\|Np\|_0^2 = (D_0 - 2r) \|p\|_0^2$. Orthogonal complements of the constructed ladders are invariant under N, F, H , so induction decomposes the full finite space. Counting degree- r vectors before the middle gives $c_r - c_{r-1}$ new primitive ladders. The isomorphism in (7.2) maps $[q(S)]$ in a chosen primitive copy to $q(\rho_\Sigma + N)p$.

S11.1.13 7.1 All symmetric packets, including collisions of sums

For an occupation list $\mathbf{n} = (n_\rho)_\rho$, $\sum n_\rho = k$, the corresponding invariant local component is

$$B_{\mathbf{n}} = \bigotimes_{\rho} \left(\mathbb{C}[z_1, \dots, z_{n_\rho}] / (z_j^{m_\rho}) \right)^{S_{n_\rho}}.$$

It retains its own canonical central idempotent even when two different occupation lists have the same sum $\sum n_\rho \rho$. Its graded dimensions c_r are counted by unscaled orbit monomials; equivalently their generating polynomial is

$$\prod_{\rho} \prod_{j=1}^{n_\rho} \frac{1 - t^{m_\rho + j - 1}}{1 - t^j}. \quad (7.6)$$

For $n_\rho = 0$ the factor is one. This is a polynomial identity for the orbit counts; no division at a root of unity is needed. The same operators preserve invariants and the same primitive proof gives (7.2) with

$$D_0 = \sum n_\rho (m_\rho - 1), \quad \rho_\Sigma = \sum n_\rho \rho$$

and these invariant c_r . It includes all k and all finite multiplicities.

For one order-three zero taken twice, write $z_i = s_i - \rho$, $X = z_1 + z_2$. The symmetric component has the exact ladders

$$1, X, X^2, X^3, X^4, \quad p = z_1^2 - z_1 z_2 + z_2^2, \quad Xp = 0, \quad (7.7)$$

with $X^3 = 3(z_1^2 z_2 + z_1 z_2^2)$ and $X^4 = 6z_1^2 z_2^2$. Its pushforward is

$$\mathbb{C}[S]/(S - 2\rho)^5 \oplus \mathbb{C}[S]/(S - 2\rho). \quad (7.8)$$

The actual total dimension is six. Merely retaining one evaluation at 2ρ would lose five dimensions; the displayed injective primitive maps and direct sum retain all six.

The original $v_h^{\otimes k}$ acts by an invertible multiplication map on every component and commutes with A_k . It carries these coordinates to the original full-jet coordinates. Its coefficients are not assigned one.

S11.1.14 8. Pairings, traces, and the support-layer meaning of the ladders

The algebraic direct image in (3.1) keeps the full underlying vector space. Therefore its trace of a^{A_k} is unchanged. On the occupation component,

$$\mathrm{Tr}(a^{A_k} \mid B_{\mathbf{n}}) = \left[\prod_{\rho} \binom{n_\rho + m_\rho - 1}{n_\rho} \right] a^{\sum n_\rho \rho}. \quad (8.1)$$

This is valid with all nonzero nilpotents, since their exponential is triangular with diagonal one. The cochain summand has degree k , so its supertrace is $(-1)^k$ times (8.1). The complementary symmetry summands retain their previously calculated traces. No packet is deleted by pushing to the sum line.

Each ladder map in (7.2) has a split lift fixing τ . In the module $\mathbb{C}[S]/(S - \rho_\Sigma)^\ell$, the transition to the quotient of length $\ell - 1$ takes the nonzero top jet to the supported zero. On its original side the quotient map is the corresponding quotient by $\mathbb{C}N^{\ell-1}p$; it is a $\mathbb{C}[S]$ -module quotient, not a declaration

that this line is an algebra ideal. The full direct-image theorem retains the line before that optional observation.

The residue pairing and arithmetic Jacobian trace form are transported by the same full coordinate matrices. For an invertible coordinate map U , retain

$$S' = U^* S U, \quad J'_g = U^{-1} J_g U, \quad G' = U^* G U, \quad S' J'_g = U^* S J_g U. \quad (8.2)$$

On product cohomology one additionally retains the original tensor-duality signs. No auxiliary inner product from (7.4) is substituted in (8.2). A supported zero of the trace and a full vanishing jet are connected only through the stated Jacobian/trace map.

S11.1.15 9. A complete unscaled arithmetic-moment calibration

For a declared Gaussian calibration, not an asserted zeta packet, take the one-variable measure $e^{-t^2/2} dt$. The change (5.2) gives

$$\mathbf{W}_2(u) = \sqrt{\pi} e^{-u^2/4} \begin{pmatrix} 1 & -2 & 12 \\ -2 & 12 & -120 \\ 12 & -120 & 1680 \end{pmatrix} \quad (9.1)$$

on coefficient functions of $1, \Delta, \Delta^2$. This uses

$$\frac{1}{2} \int v^{2j} e^{-v^2/4} dv = 2^j (2j-1)!! \sqrt{\pi},$$

with $(-1)!! = 1$. The actual triangular coordinate matrix with columns $1, \Delta + 2, \Delta^2 + 12\Delta + 12$ is

$$T = \begin{pmatrix} 1 & 2 & 12 \\ 0 & 1 & 12 \\ 0 & 0 & 1 \end{pmatrix}, \quad T^* \mathbf{W}_2(u) T = \sqrt{\pi} e^{-u^2/4} \text{diag}(1, 8, 384). \quad (9.2)$$

All three fibre directions and their norms survive. For the first two directions, the exact base/relative decomposition is

$$\|f_0 + \Delta f_1\|^2 = \sqrt{\pi} \int e^{-u^2/4} (|f_0 - 2f_1|^2 + 8|f_1|^2) du. \quad (9.3)$$

The source metric has total two-variable mass 2π , retained by these formulas. Exact symbolic tests compare the moments of $S^a \Delta^b$ computed directly in (t_1, t_2) and through (9.1), and compare the resulting constrained representatives, jet maps, Grams and controls.

For the actual arithmetic measure, (5.3) supplies the corresponding nonconstant matrix. Its relative covariance need not have the constant Gaussian form. Neither the calibration's triangular coefficients nor its control are imported into the arithmetic case.

S11.1.16 10. Position in the Deligne-style programme

The source's tensor-square step is followed by geometric pushforward and control on that pushforward, not by tensoring alone. The construction here now supplies a **specified sum-coordinate pushforward** of the actual finite arithmetic image and its original filtered representatives. Its metric realization is the exact one-dimensional matrix weight (5.3) or (5.6), with the relative directions retained. The symmetric relation presentation (4.4) and original primitives (4.7) say exactly which zero-amplitude relations are present in that fibre.

The result does not identify this finite spectral scheme or matrix-weight model with a lisse sheaf on a Lefschetz pencil. The map actually constructed is the quasi-coherent finite pushforward (3.1), connected to the original analytic representatives by (2.3), (4.8), and (5.4). Deligne’s geometric hypotheses and estimates have not thereby been imported.

The immediate control task now has an explicit base/relative split: estimate the actual convolution mass, the full relative covariance, and the full-jet interpolation on the **image** of the filtered polynomial family in (6.4). These determine the same $K_M, \mathcal{Z}_M$ as the preceding work. The sum map retains A_k and every repeated eigenline, so a bound sublinear in k would still have the intended force. No such bound is proved in this note.

The concrete advances are the exact filtered symmetric relation algebra, an all- k spectral-sum norm realization, and a full nilpotent direct-image decomposition that retains multiplicities and colliding occupations. They are new applications to this specified programme; the reusable algebra and integration tools are standard and are not asserted to be globally novel.

S12.1 Quantitative sum-fibre connection and the conormal arithmetic trace

Owner-directed continuation of the split-zero programme, 12 September 2026.

Status. Written analytic and algebraic deductions for review. The original theta source, its asserted range theorem, and the canonical finite representatives are inputs from the preceding work. No new Lean execution or arithmetic purity theorem is claimed. The new analytic estimate is a mass-retaining contraction for the actual spectral-sum density. The full matrix connection, its normal component, and the conormal derivative of the original theta relations are constructed as well; the contraction is not assigned to the full Weil control form without a comparison.

S12.1.1 1. Source intake and the unchanged marked object

The newly uploaded Kernel Layer Integration archive is byte-identical to its earlier uploaded copy. Its thirty-one manifest entries and the fifty-three entries in the Spectral Sum Descent archive were independently verified. The kernel-layer note's identities are used as source results, not counted as new deductions:

$$K_M = G_M^{-1}, \quad V_M = A_k K_M + K_M A_k^* - k K_M, \quad W_M = G_M V_M G_M. \quad (1.1)$$

In particular the same control problem is transported by the actual map $v = K_M \lambda$. The source's next theta-relation layer, its full-jet columns, and its map into B_{M+1}/B_M remain attached. Its formalization interface is the existing internal quotient, not a replacement quotient.

Retain the marked absolute base $\mathfrak{b}_\tau$, the scalar semiring, and the original infinite quotient:

$$G(R) = \{\tau\} \sqcup \{r^\bullet : r \in R\}, \quad e_R = 0_R^\bullet, \quad \begin{array}{ccc} G(\mathbb{Z}) & \xrightarrow{G(j)} & G(\mathbb{C}) \\ p_{\mathbb{Z}} \downarrow & & \downarrow p_{\mathbb{C}} \\ \mathbb{Z} & \xrightarrow{j} & \mathbb{C}. \end{array} \quad (1.2)$$

The target of $p_{\mathbb{Z}}$ is infinite. Every ring map below is lifted through G and this square. A complex-linear map $T : V \rightarrow W$ is lifted instead by the explicitly defined split-linear map $T^\tau(v^\bullet) = (Tv)^\bullet$, $T^\tau(\tau) = \tau$. These are different types of construction, connected by their respective arithmetic projection squares. In the full support diagram the same formula is $(\lambda, v) \mapsto (\varphi(\lambda), T_\lambda v)$, with the displayed support transport φ . In particular amplitude zero is the receiving fibre's zero, not external absence.

The original test spaces and operators are

$$\begin{aligned} V &= \{\phi \in \mathcal{S}(\mathbb{R}) : \phi \text{ even}, \phi(0) = 0, \int_{\mathbb{R}} \phi = 0\}, \\ \mathcal{B} &= \{F \in C^\infty(\mathbb{R}_{>0}) : \sup_{x>0} x^b |D^j F(x)| < \infty \ (b \in \mathbb{Z}, j \geq 0)\}, \quad D = -x\partial_x, \\ C_+ &= [V \xrightarrow{\Theta} \mathcal{B}], \quad \Theta\phi(x) = \sum_{n \neq 0} \phi(nx), \quad Q = \mathcal{B}/\Theta V, \\ \phi_* &= (4\pi^2 x^4 - 6\pi x^2)e^{-\pi x^2}, \quad g(s) = 2\xi(s), \quad \mathcal{M}\Theta\phi = gH_\phi, \quad H_{\phi_*} = 1. \end{aligned} \quad (1.3)$$

Fix a finite packet of actual zeros with full multiplicities, stable under $\rho \mapsto 1 - \bar{\rho}$. Put

$$h(s) = \prod_{\rho \in Z} (s - \rho)^{m_\rho}, \quad d = \deg h, \quad v_h = g/h, \quad E_h = \mathbb{C}[s]/(h), \quad v_h = j_h v_h \in E_h^\times. \quad (1.4)$$

The source supplies $F_h \in \mathcal{B}$ with $\mathcal{M}F_h = v_h$ and $h(D)F_h = \Theta\phi_*$. It also supplies

$$\mathcal{T}_h P = P(D)F_h, \quad \mathcal{T}_h(hP) = \Theta(P(D)\phi_*), \quad J_h \mathcal{T}_h P = v_h[P]_h. \quad (1.5)$$

The statements below also apply to $h = 1$ as the actual theta-seed calculation, but that case has zero-dimensional arithmetic quotient and is not substituted for a nonempty packet.

S12.1.2 2. The sum coordinate and its conjugate logarithmic operator

Let $k \geq 2$, $S = \sum_{i=1}^k s_i$, and use the explicit centered relative coordinates

$$z_i = s_i - S/k \quad (i < k), \quad z_k = -\sum_{i < k} z_i, \quad s_i = S/k + z_i. \quad (2.1)$$

On the original integration lines set

$$s_i = \frac{1}{2} + it_i, \quad S = \frac{k}{2} + iu, \quad u = \sum_i t_i, \quad y_i = t_i - u/k \ (i < k), \quad y_k = -\sum_{i < k} y_i. \quad (2.2)$$

The inverse is $t_i = u/k + y_i$. The real Jacobian has absolute value one. For $k = 2$, the earlier relative coordinate was $v = t_1 - t_2 = 2y_1$, so $dt_1 dt_2 = du dy_1 = \frac{1}{2} du dv$. Thus the earlier factor $1/2$ remains exactly in that coordinate comparison. Its Δ is $4z_1^2 = -4y_1^2$.

Write

$$a_h(t) = \frac{v_h(\frac{1}{2} + it)}{\sqrt{2\pi}}, \quad w_h(t) = |a_h(t)|^2, \quad \mu_h = \int_{\mathbb{R}} w_h(t) dt = \|F_h\|_{L^2(dx)}^2. \quad (2.3)$$

The factor $\sqrt{2\pi}$ is the stated Mellin–Fourier Plancherel factor. No mass has been set to one. Define the actual fibre amplitude

$$\Psi_k(u, \mathbf{y}) = \prod_{i=1}^k a_h(u/k + y_i). \quad (2.4)$$

Mellin–Fourier followed by (2.2) is the unitary map

$$\mathcal{U}_k : L^2(\mathbb{R}_{>0}^k, d^k x) \longrightarrow L^2(\mathbb{R}_u \times \mathbb{R}_{\mathbf{y}}^{k-1}, du d\mathbf{y}).$$

On the given test functions it satisfies

$$\begin{aligned} \mathcal{U}_k(D^{(k)}F) &= (\tfrac{k}{2} + iu)\mathcal{U}_kF, \quad D^{(k)} = \sum_i D_i, \\ \partial_u \mathcal{U}_kF &= i\mathcal{U}_k(\mathcal{L}_kF), \quad \mathcal{L}_k = \frac{1}{k} \sum_{i=1}^k \log x_i, \quad [D^{(k)}, \mathcal{L}_k] = -1. \end{aligned} \quad (2.5)$$

Here $\mathcal{L}_k$ is multiplication by the displayed function; $1/k$ comes from the inverse coordinate map keeping the relative z_i fixed. It does not change the scaling generator $D^{(k)}$. The identities follow by differentiating the Mellin integral. Logarithmic multiplication preserves $\mathcal{B}$ and the corresponding tensor test space.

For the polynomial source,

$$\mathcal{U}_k \mathcal{T}_h^{(k)} P = \Psi_k(u, \mathbf{y}) P(S/k + iy_1, \dots, S/k + iy_k). \quad (2.6)$$

Thus the operator whose new estimate is computed is related to the original scaling operator by the precise commutator (2.5), not equated with the generator or its weight defect.

S12.1.3 3. A quantitative contraction on the actual arithmetic density

Define the convolution mass and its logarithmic-derivative energy by

$$\begin{aligned} m_k(u) &= \int_{\mathbb{R}^{k-1}} |\Psi_k(u, \mathbf{y})|^2 d\mathbf{y} = w_h^{*k}(u), \quad \int m_k = \mu_h^k, \\ \mathcal{I}_h &= \int_{\mathbb{R}} \frac{|w'_h(t)|^2}{w_h(t)} dt, \quad \mathcal{I}_{h,k} = \int_{\mathbb{R}} \frac{|m'_k(u)|^2}{m_k(u)} du. \end{aligned} \quad (3.1)$$

At isolated zeros of w_h , the integrand is assigned its limiting value where applicable, or any value on that null set. The construction and proofs use the smooth amplitude a_h , so no division at a zero is required. For $k \geq 2$, $m_k(u) > 0$ for every real u : each factor w_h is positive almost everywhere, and its convolution integral has a positive integrand almost everywhere on its fibre.

The original functional equation gives

$$g^\dagger = g, \quad h^\dagger = (-1)^d h, \quad v_h^\dagger = (-1)^d v_h, \quad \overline{a_h(t)} = (-1)^d a_h(t). \quad (3.2)$$

Accordingly a_h and a'_h have the same fixed real/imaginary phase and

$$\boxed{\mathcal{I}_h = 4 \int_{\mathbb{R}} |a'_h(t)|^2 dt = 4 \int_0^\infty (\log x)^2 |F_h(x)|^2 dx < \infty, \quad \int \overline{a_h} a'_h = 0.} \quad (3.3)$$

Proof: outside the discrete zero set, $w'_h = 2\overline{a_h}a'_h$ is real, giving $w_h'^2/w_h = 4|a'_h|^2$. Mellin Plancherel and $\partial_t v_h(\frac{1}{2} + it) = i v'_h(\frac{1}{2} + it)$ give the second equality. The zero integral is the integral of $w'_h/2$. The decay needed at both endpoints follows from $F_h \in \mathcal{B}$: $e^{y/2} F_h(e^y)$ is Schwartz, as are its polynomially weighted versions. Reflection (3.2) is essential for the equality rather than just an upper bound.

Let $\mathcal{H}_u = L^2(\mathbb{R}^{k-1}, d\mathbf{y})$. The line inclusion and projection are

$$j_{0,u} : \mathbb{C} \rightarrow \mathcal{H}_u, \quad c \mapsto c\Psi_k(u, \cdot), \quad \Pi_{0,u}Z = \Psi_k \frac{\langle \Psi_k, Z \rangle}{m_k(u)}.$$

Put

$$n_k(u) = (1 - \Pi_{0,u})\partial_u \Psi_k = \partial_u \Psi_k - \frac{m'_k}{2m_k} \Psi_k. \quad (3.4)$$

The inner product is antilinear in its first argument. Equation (3.2) makes $\langle \Psi_k, \partial_u \Psi_k \rangle = m'_k/2$ real. Therefore (3.4) is precisely an orthogonal decomposition, including at zeros of individual amplitude factors.

Theorem 3.1 (mass-retaining sum contraction and exact relative term).

$$\mathcal{I}_{h,k} + 4 \int_{\mathbb{R}} \|n_k(u)\|_{\mathcal{H}_u}^2 du = \frac{\mu_h^{k-1}}{k} \mathcal{I}_h. \quad (3.5)$$

In particular

$$\mathcal{I}_{h,k} \leq \frac{\mu_h^{k-1}}{k} \mathcal{I}_h. \quad (3.6)$$

Proof. Differentiate the actual product amplitude in the centered coordinates:

$$\partial_u \Psi_k = \frac{1}{k} \sum_{i=1}^k a'_h(t_i) \prod_{j \neq i} a_h(t_j).$$

Integrating its squared modulus over all original t_i , the k diagonal terms each give $\mu_h^{k-1} \|a'_h\|^2$. Every distinct-index cross term is $\mu_h^{k-2} |\int \overline{a_h} a'_h|^2 = 0$. Thus

$$\int \|\partial_u \Psi_k\|^2 du = \frac{\mu_h^{k-1}}{4k} \mathcal{I}_h.$$

The pointwise orthogonal decomposition (3.4) gives

$$\|\partial_u \Psi_k\|^2 = \frac{m_k'^2}{4m_k} + \|n_k\|^2.$$

Integrate and multiply by four. This proves both statements and the finiteness of $\mathcal{I}_{h,k}$. All masses and the factor four remain.

This is an application of the projection mechanism underlying Fisher-information convolution inequalities (Johnson–Barron), with the actual arithmetic amplitude, its phase, and its residual relative vector kept explicitly. It does not rely on log-concavity, a Gaussian approximation, or locations of the zeros beyond the stipulated reflection-stable packet and the source construction of F_h .

The pair $(\Pi_{0,u}\partial_u \Psi_k, n_k)$ retains the full derivative by addition. Its split lift can have an active zero in either component without converting the other component or its source to τ . Dropping n_k would replace equality (3.5) by an inequality and lose the quantified relative contribution; the actual projection and its complementary map remain available.

S12.1.4 4. The full relative matrix has a computed connection and normal variation

Take any finite linearly independent family of relative polynomials $\theta_\alpha(\mathbf{z})$, independent of S . For the original degree- M source use the actual coefficient functions

$$P(\mathbf{s}) = \sum_{\alpha} \theta_{\alpha}(\mathbf{z}) f_{\alpha}(S), \quad \deg f_{\alpha} \leq M - \deg \theta_{\alpha}. \quad (4.1)$$

Choose a homogeneous relative monomial basis, or the stated unscaled invariant basis on a symmetric summand, so that these degree conditions specify the exact original filtered image. This is the centered-coordinate version of the preceding matrix weight; substitution $s_i = S/k + z_i$ is triangular by total degree and invertible.

Define the actual fibre map, its derivative, and its three Gram matrices:

$$\begin{aligned} j_u : \mathbb{C}^r &\rightarrow \mathcal{H}_u, & j_u c &= \Psi_k(u, \mathbf{y}) \sum_{\alpha} \theta_{\alpha}(i\mathbf{y}) c_{\alpha}, \\ W(u) &= j_u^* j_u, & B(u) &= j_u^* j'_u, & T(u) &= (j'_u)^* j'_u. \end{aligned} \quad (4.2)$$

These are integrals in the same arithmetic measure. $W(u)$ is strictly positive because the relative polynomials are independent and Ψ_k is nonzero almost everywhere. Every entry is smooth by differentiated Schwartz estimates on compact u intervals. Its domain has its stated finite size r ; no assertion is made that r remains fixed as the source degree grows.

In the fixed-phase case (3.2),

$$B(u) = \frac{1}{2} W'(u). \quad (4.3)$$

Indeed $\overline{\Psi_k} \partial_u \Psi_k$ is real almost everywhere, hence B is Hermitian; differentiate W to get $W' = B + B^*$. The integrals remain valid at the zero set because the smooth product amplitude, not its logarithm, is used.

Let

$$\Pi_u = j_u W^{-1} j_u^*, \quad \Gamma_u = W^{-1} B = \frac{1}{2} W^{-1} W', \quad N_u = (1 - \Pi_u) j'_u. \quad (4.4)$$

The exact differential map is

$$\boxed{\partial_u(j_u c(u)) = j_u(c'(u) + \Gamma_u c(u)) + N_u c(u), \quad j_u^* N_u = 0.} \quad (4.5)$$

Thus $\nabla_u c = c' + \Gamma_u c$ is a metric-compatible connection on this finite coefficient bundle:

$$\Gamma_u^* W + W \Gamma_u = W'. \quad (4.6)$$

The complete normal form is

$$\boxed{\mathcal{N}(u) := N_u^* N_u = T - B^* W^{-1} B = T - \frac{1}{4} W' W^{-1} W' \succeq 0.} \quad (4.7)$$

In particular no commutation of W and W' is assumed. Multiplication proves the identity and positivity follows from $1 - \Pi_u$ being an orthogonal projection. The norm decomposition is

$$\boxed{\|\partial_u(j_u c)\|^2 = (\nabla_u c)^* W (\nabla_u c) + c^* \mathcal{N} c.} \quad (4.8)$$

For the one-column constant family, (4.8) is exactly (3.5) before integration. For the full relative family it retains every matrix entry in both terms. Scalar inequality (3.6) is not inserted as a bound

on this larger matrix: its precise connection is the inclusion of the constant column and the pair of projections $\Pi_{0,u}, \Pi_u$ with $\text{im } \Pi_{0,u} \subset \text{im } \Pi_u$.

S12.1.5 Change of relative frame

For an explicitly given invertible smooth matrix $C(u)$, replace the fibre map by $j_u^C = j_u C(u)$. The exact transformed connection and normal map are

$$W^C = C^* W C, \quad \Gamma^C = C^{-1} \Gamma C + C^{-1} C', \quad N^C = N C. \quad (4.12)$$

These follow by differentiating j^C and applying the same orthogonal projection. This is the additional derivative term needed when using the earlier pointwise triangular square-completion map, whose coefficients can depend on u . Multiplication by S still intertwines without such a term; the derivative's relationship to it is the explicit commutator (2.5). The exact filtered image of the original coefficient functions is retained after this change of frame.

S12.1.6 4.1 The differentiated filtered image is retained

For the actual source coefficient function $c_P(u) = (f_\alpha(k/2 + iu))_\alpha$, define the linear graph map

$$\mathcal{D}_M : P \mapsto (j_u \nabla_u c_P, N_u c_P). \quad (4.9)$$

Its values lie in the specified graph image $\mathcal{G}_M$, not in two freely chosen function spaces. Addition of the two components recovers

$$\text{Add } \mathcal{D}_M(P) = \partial_u \mathcal{U}_k \mathcal{T}_h^{(k)} P = i \mathcal{U}_k \mathcal{L}_k \mathcal{T}_h^{(k)} P. \quad (4.10)$$

The two summands are pointwise orthogonal, so this addition is an isometric injection on the graph into the derivative's actual image. This supplies a precise way to recover its arithmetic jet:

$$\mathcal{G}_M \xrightarrow{\text{Add}} i \mathcal{U}_k (\mathcal{B}^{\widehat{\otimes} k}) \xrightarrow{-i \mathcal{U}_k^{-1}} \mathcal{B}^{\widehat{\otimes} k} \xrightarrow{J^{(k)}} E_h^{\otimes k}. \quad (4.11)$$

No separate arithmetic-jet map on an arbitrary measurable normal section is asserted. The combined graph is exactly the domain on which the formula is defined. The original support label is retained in both components and in (4.11). The cohomological control still uses A_k, R_M, G_M, W_M and (1.1); (2.5), (4.10), and (4.11) are the actual comparison to this new analytic derivative.

S12.1.7 5. Differentiating a supported relation requires its first infinitesimal layer

The logarithmic observable in (2.5) has a calculated effect on the original theta relation, even in one variable:

$$\boxed{J_h(\log x \Theta \phi) = j_h(g') j_h(H_\phi)}. \quad (5.1)$$

Proof: logarithmic multiplication differentiates the actual Mellin transform, so

$$\mathcal{M}(\log x \Theta \phi) = g' H_\phi + g H'_\phi.$$

Taking full jets modulo h removes the second term, but not the first. For $\phi = P(D)\phi_*$, $H_\phi = P$; hence all E_h values of $j_h H_\phi$ are supplied by actual original source functions.

This is the map connecting the original supported boundary to the Jacobian trace contraction. In the original quotient $q\Theta = 0$, while $J_h(\log x \Theta)$ has the explicitly displayed image. The typed resolution of that effect is a first thickening of the *same* relation ideal.

Put

$$\mathcal{P} = \mathbb{C}[s_1, \dots, s_k], \quad I = (h(s_1), \dots, h(s_k)), \quad E = \mathcal{P}/I, \quad E^{[2]} = \mathcal{P}/I^2.$$

There is the actual exact sequence

$$0 \longrightarrow I/I^2 \longrightarrow E^{[2]} \xrightarrow{\pi} E \longrightarrow 0. \quad (5.2)$$

The coefficient conormal map is the isomorphism

$$\iota_N : E^k \xrightarrow{\sim} I/I^2, \quad (a_1, \dots, a_k) \mapsto \left[\sum_i h(s_i) \tilde{a}_i \right]. \quad (5.3)$$

A direct proof uses monic division in each variable. The polynomial ring is free over $\mathbb{C}[h(s_1), \dots, h(s_k)]$ with basis $\prod s_i^{a_i}$, $0 \leq a_i < d$. Modulo the square of the ideal of these latter variables, only coefficient degrees zero and one survive. This proves uniqueness and surjectivity in (5.3), retaining all nilpotents in E .

Define the sum derivative at fixed relative coordinates

$$\partial_S^{\text{rel}} = \frac{1}{k} \sum_i \partial_{s_i}. \quad (5.4)$$

It maps I^2 into I , so it induces a *complex-linear* map

$$\delta_S : E^{[2]} \longrightarrow E, \quad [P]_{I^2} \mapsto [\partial_S^{\text{rel}} P]_I. \quad (5.5)$$

It is a derivation along π :

$$\delta_S(ab) = \pi(a)\delta_S(b) + \pi(b)\delta_S(a), \quad \delta_S(S) = 1.$$

Its restriction to the retained conormal fibre is the E -linear row

$$\delta_S \iota_N(a_1, \dots, a_k) = \frac{1}{k} \sum_i h'(s_i) a_i. \quad (5.6)$$

The full conormal differential, before contraction by ∂_S^{rel} , is

$$I/I^2 \xrightarrow{d_I} \bigoplus_i E \, ds_i, \quad (a_i)_i \mapsto \sum_i h'(s_i) a_i \, ds_i. \quad (5.7)$$

This is the two-term cotangent presentation for the complete intersection, in cohomological degrees $-1, 0$. Its universal differential and (5.5) are related by contraction $\sum b_i ds_i \mapsto k^{-1} \sum b_i$. This is the established conormal/cotangent construction applied to this exact packet ideal (Stacks, Tags 00S0 and 08SH).

The original split diagram is

$$G(E^{[2]}) \xrightarrow{G(\pi)} G(E), \quad \delta_S^\tau : G(E^{[2]}) \longrightarrow G(E) \quad \text{as } G(\mathbb{C})\text{-semimodules.} \quad (5.8)$$

The first is a semiring morphism; the second is a split-linear map of coefficient modules, not a semiring morphism. Both send external absence to external absence and supported zero to supported zero. A supported conormal class has image e_E under the first map, while its image under the second is the supported scalar specified in (5.6). The larger domain retains the datum needed to differentiate that relation.

For one local block $h = (s - \rho)^m$ times a retained unit, (5.6) detects the z^{m-1} coefficient with its factor m . In an ordered product of local block lengths m_i , the image of (5.6) has dimension

$$\prod_i m_i - \prod_i (m_i - 1), \quad (5.9)$$

because it is the ideal generated by the unit multiples of $z_i^{m_i-1}$. Each unit is invertible in its actual local algebra. Monomials missing all top exponents form the complementary vector count; they are not discarded from E .

S12.1.8 5.1 Carry the arithmetic jet unit through the derivative

Let $U(\mathbf{s}) = \prod_i v_h(s_i)$, and retain its full Taylor class $\widehat{U} \in E^{[2]}$. This class is invertible. Define

$$\widehat{\mathcal{J}}P = \widehat{U}[P]_{I^2}, \quad \mathcal{J}P = U[P]_I, \quad \beta_h = U^{-1}\delta_S\widehat{U} \in E. \quad (5.10)$$

The finite Taylor realization here uses the entire functions on neighbourhoods of the finite zero set; polynomial Hermite interpolation supplies their classes. $E^{[2]}$ is *not* being called a new zeta-zero packet: it also retains first-order source relations not annihilated by g .

The exact commuting equation is

$$\boxed{J^{(k)}\mathcal{L}_k\mathcal{T}_h^{(k)}P = \delta_S\widehat{\mathcal{J}}P = \mathcal{J}(\partial_S^{\text{rel}}P) + \beta_h\mathcal{J}P.} \quad (5.11)$$

Proof: its Mellin transform is $\partial_S^{\text{rel}}(UP)$. Apply the product rule before taking jets. Thus the coefficient-connection term is $\beta_h = k^{-1}\sum_i j(v'_h/v_h)(s_i)$, with no discarded local unit.

For an original relation $P = \sum_i h(s_i)P_i$, the last term vanishes and

$$\boxed{J^{(k)}\mathcal{L}_k\mathcal{T}_h^{(k)}P = \frac{1}{k}U\sum_i h'(s_i)[P_i]_I.} \quad (5.12)$$

Modulo I , $v_h(s_i)h'(s_i) = g'(s_i)$, so the same equation can be written with $g'(s_i)$ and the other retained v_h factors. This is the precise relationship between the analytic sum derivative in (4.10) and the conormal row (5.6).

In one variable the source's residue pairing therefore obeys

$$\boxed{\mathcal{R}_Z(f, J_h(\log x \Theta(P(D)\phi_*))) = \sum_{\rho \in Z} m_\rho \overline{f(1 - \bar{\rho})} P(\rho).} \quad (5.13)$$

Indeed (5.1) makes the second argument $g'P$, and g'/g has residue m_ρ . The residue pairing, its Jacobian contraction, and the logarithmic derivative of an actual original theta relation have now been connected by a single formula. No new positivity assertion is inferred from that equality.

S12.1.9 6. All higher derivative layers and the old cochain signs remain available

For $r \geq 1$, the derivation gives actual maps

$$\partial_S^{\text{rel}} : \mathcal{P}/I^{r+1} \longrightarrow \mathcal{P}/I^r. \quad (6.1)$$

They commute with the quotient maps wherever their sources and targets match. The associated-graded algebra is explicitly

$$\text{gr}_I \mathcal{P} \cong E[\eta_1, \dots, \eta_k], \quad \eta_i \longleftrightarrow [h(s_i)]. \quad (6.2)$$

On it, the degree-minus-one derivative is

$$\boxed{\text{gr}(\partial_S^{\text{rel}}) = \frac{1}{k} \sum_i h'(s_i) \partial_{\eta_i}.} \quad (6.3)$$

The proof expands $\partial(h^\alpha P)$. The term differentiating P stays in $I^{|\alpha|}$ and disappears only in the explicitly specified quotient $I^{|\alpha|-1}/I^{|\alpha|}$. The other terms give (6.3) with every factor α_i retained. Consequently this layer has rank $\binom{r+k-1}{k-1}$ over E , not one new scalar support.

There is also a full mixed derivative formula retaining all coordinate directions:

$$\boxed{\left[\partial_{s_1} \cdots \partial_{s_k} \left(UP \prod_i h(s_i) \right) \right]_I = \left[UP \prod_i h'(s_i) \right]_I = \left[P \prod_i g'(s_i) \right]_I.} \quad (6.4)$$

Every other product-rule term contains an undifferentiated $h(s_i)$ and maps to the supported zero in E . At the test-function level these derivatives are multiplication by $\prod_i \log x_i$. At the residue level (6.4) is the product Jacobian in the existing tensor arithmetic trace. The ordered volume form $ds_1 \wedge \cdots \wedge ds_k$ and the previously specified tensor-duality sign are retained; no new identification of the iterated residue with an unsigned cochain supertrace is made.

The original primitive of $h(s_i)P_i$ still has the sign $(-1)^{i-1}$ from the prior product complex. Its cochain differential supplies the second $(-1)^{i-1}$. Conormal reduction records the resulting coefficient $[P_i]_I$. It does not replace that source primitive or the higher syzygies of its Koszul complex.

For a finite total-degree relation space, (6.1) is applied to the image of that exact space in $\mathcal{P}/I^{r+1}$. It does not enlarge the set of admissible representatives. The degree- M next-relation map from the attachment feeds (5.12) by its actual polynomial numerator. This supplies a differentiated observation of those very same e -relations.

S12.1.10 7. Exact calibrations and a bounded arithmetic seed evaluation

S12.1.11 7.1 Gaussian fibre: the relative connection can be flat without deleting it

Take the declared calibration $a(t) = e^{-t^2/4}$, $w(t) = e^{-t^2/2}$, $\mu = \sqrt{2\pi}$. This is a test of the formula, not the arithmetic input. For two factors,

$$\Psi_2(u, y) = e^{-u^2/8} e^{-y^2/2}, \quad m_2(u) = \sqrt{\pi} e^{-u^2/4}.$$

For every fixed relative polynomial frame, $j'_u = -(u/4)j_u$, so

$$\Gamma_u = -\frac{u}{4}I, \quad \mathcal{N}(u) = 0, \quad \mathcal{I}_2 = \frac{\mu \mathcal{I}_1}{2} = \pi. \quad (7.1)$$

All relative directions and their Gram entries remain; zero normal variation is a proved consequence of this particular product, not an instruction to erase the relative fibre in the arithmetic case.

S12.1.12 7.2 A zero-bearing calibration has nonzero retained normal variation

Take instead $a(t) = te^{-t^2/4}$ and $w(t) = t^2e^{-t^2/2}$. Then

$$\begin{aligned}\mu &= \sqrt{2\pi}, & \mathcal{I}_1 &= 3\sqrt{2\pi}, \\ \Psi_2(u, y) &= (u^2/4 - y^2)e^{-u^2/8 - y^2/2}, \\ m_2(u) &= \frac{\sqrt{\pi}}{16}e^{-u^2/4}(u^4 - 4u^2 + 12).\end{aligned}\tag{7.2}$$

These identities follow from the complete Gaussian even moments; the polynomial has positive minimum 8, so m_2 has no zero. For $u \neq 0$, $\partial_u \Psi_2$ is not a multiple of Ψ_2 as a polynomial in y , so $n_2(u) \neq 0$. The exact identity is

$$\mathcal{I}_2 + 4 \int \|n_2\|^2 = 3\pi, \quad \mathcal{I}_2 < 3\pi.\tag{7.3}$$

The checker calculates the two-column matrix connection and nonzero positive normal Gram at $u = 1$, retaining the relative basis and its mass factors. This also tests the handling of zeros without assuming logarithmic scores are bounded.

S12.1.13 7.3 The actual arithmetic seed, with no selected zero coordinates

For $h = 1$, $F_h = f_0 = \Theta\phi_*$. Its exact inversion is $f_0(x) = x^{-1}f_0(1/x)$. Hence

$$\mu_1 = 2 \int_1^\infty f_0(x)^2 dx, \quad \mathcal{I}_1 = 8 \int_1^\infty (\log x)^2 f_0(x)^2 dx.\tag{7.4}$$

On that half-line use the actual absolutely convergent sum

$$f_0(x) = 2 \sum_{n \geq 1} (4\pi^2 n^4 x^4 - 6\pi n^2 x^2) e^{-\pi n^2 x^2}.$$

The numerical evaluations at 45 digits with six integer terms and at 65 digits with eight integer terms agree on the displayed 35-digit values:

$$\mu_1 \approx 1.2790072478464851404795335922671933, \quad \mathcal{I}_1 \approx 0.12575246821348846545509759756793817.$$

The optional computation evaluates (7.4) at two stated decimal precisions and two integer cutoffs. Its output is labeled numerical, not an interval certificate. The theorem uses the exact integrals; no numerical value or cutoff is imported into a purity assertion.

S12.1.14 8. What the new estimate controls in the programme

The earlier arithmetic defect remains

$$W_M = A_k^* G_M + G_M A_k - k G_M, \quad V_M = A_k K_M + K_M A_k^* - k K_M, \quad W_M = G_M V_M G_M. \tag{8.1}$$

The new operations retain the path

$$\mathcal{T}_k(P) \xrightarrow{\mathcal{U}_k} \Psi_{kCP} \xrightarrow{\partial_u} \mathcal{G}_M \xrightarrow{\text{Add}, -i\mathcal{U}_k^{-1}} \mathcal{L}_k \mathcal{T}_k(P) \xrightarrow{J^{(k)}} \delta_S \hat{\mathcal{J}} P. \tag{8.2}$$

This is the explicit connection between the positive differential estimate, the matrix-valued relative fibre, and the first conormal layer of the original arithmetic quotient. It does not replace the scaling generator A_k with differentiation. Their relation is the commutator (2.5), and the source's original representative relation $D^{(k)}R_M - R_MA_k \in B_{M+1}$ continues to determine (8.1).

The result of this continuation is a genuine $1/k$ factor in (3.5), with the literal mass μ_h^{k-1} , and an exact decomposition of the full matrix derivative. Uniform relative interpolation control is still needed to transfer that integrated smoothing to the extremal finite-packet estimate (8.1). The required comparison cannot be inferred from the scalar density alone; (4.9)–(4.11) and (5.11) provide the actual objects on which to work. All normal terms and the conormal Jacobian remain in that comparison.

Deligne's source architecture requires a further estimate after the product-to-one-parameter operation, on the same arithmetic image and with its duality. This note constructs and estimates a differential of that new-base pushforward, and identifies its exact interaction with the trace-producing Jacobian. It does not assert that a Fisher inequality is already Deligne purity, or that the analytic matrix bundle is a finite-field lisse sheaf. The finite-point cohomology, spectral-sum restriction functor, kernel-layer calculation, and first infinitesimal quotient remain connected by the typed arrows above.

S12.1.15 References and reading record

1. Supplied *Tau Kernel Layer Integration*, NOTE.tex and RESEARCH_NOTE.md, read for the original relation-layer and antidual comparisons; the archive matched the earlier copy exactly and all manifest entries verified. The source's eighteen-method exact suite was rerun normally and with optimized Python. This is not a new formal certificate.
2. Supplied *Tau Spectral Sum Descent*, NOTE.tex, read in full, especially §§2, 5, 6, 8 and 10. The same sum coordinate, matrix density, relative polynomial image, full jets, and residue comparison are used.
3. Supplied *SplitZero: reconstruction, internal homology, and balanced finite jets*, §§1–4, for the existing original internal quotient and supported cohomology interfaces. No new scalar implementation is introduced.
4. Oliver Johnson and Andrew Barron, *Fisher Information inequalities and the Central Limit Theorem*, arXiv:math/0111020, published in Probability Theory and Related Fields 129 (2004), 391–409. Their projection method is established background; Theorem 3.1 is proved here directly with the unaltered arithmetic mass and phase. <https://arxiv.org/abs/math/0111020>.
5. The Stacks Project, Tags 00S0 and 08SH, the conormal presentation and cotangent complex of a local complete intersection. These are reusable algebraic constructions; the explicit arithmetic conormal row and the trace connection are computed in §§5–6. <https://stacks.math.columbia.edu/tag/00S0> and <https://stacks.math.columbia.edu/tag/08SH>.
6. Deligne, *La conjecture de Weil II*, IHES 52 (1980), 137–252. This continuation relies on the previously identified tensor/pushforward/dual-control architecture, not a fresh reading or independent audit of all pages. No finite-field theorem is asserted on the new base merely from terminology.

S13 Cyclic arithmetic sum control and the complete contracted relation tower

Source attribution. Complete TeX witness supplied in the Cyclic Sum Control archive. Its exact source and archive hashes identify the delivered text. The seven retained prior source files are identified separately; the earlier 48-entry validation claim concerns the separate Sum Connection archive. The new 24-method finite checker has a separate independent replay record. No Lean execution, remote CI or uniform arithmetic estimate is inferred from this source witness.

S13.1 Sum-generated arithmetic cohomology, scalar control, and exact conormal depth

Owner-directed continuation of the split-zero programme — 12 September 2026.

Status. Written deductions for mathematical review. This note uses the original theta source and its stated finite-packet realization from the preceding work. It does not claim a new Lean certificate, a global comparison-kernel theorem, or a uniform arithmetic purity estimate. The new constructions are (i) an explicitly injected sum-generated arithmetic submodule containing every amplified spectral value, (ii) its scalar convolution norm and rank-two control formula, (iii) raw-moment formulas for the complete differentiated polynomial image, and (iv) the exact contraction of every original conormal thickening to that sum coordinate. The full relative quotient, its action, and its trace are retained.

S13.1.1 1. Source intake and fixed objects

The two new transcript files were searched for changes to the arithmetic/control and formalization interfaces. They preserve the earlier full-jet kernel/layer calculations and the formalized internal quotient; they do not supply a later analytic proof of the remaining estimate. The previous Tau_Sum_Connection_Control archive was opened directly, its LaTeX and mathematical note were read, and all 48 entries of its supplied manifest verified. Its scalar contraction and matrix connection are inputs [S1], not attributed to the present continuation. The previous transcript's checked algebraic interfaces remain within their reported scope [S2–S4].

The original base is still b_τ . Retain

$$G(R) = \{\tau\} \sqcup \{r^\bullet : r \in R\}, \quad e_R = 0_R^\bullet,$$

$$\begin{array}{ccc}
G(\mathbb{Z}) & \xrightarrow{G(j)} & G(\mathbb{C}) \\
p\mathbb{Z} \downarrow & & \downarrow p\mathbb{C} \\
\mathbb{Z} & \xrightarrow{j} & \mathbb{C}.
\end{array} \tag{1.1}$$

The target of $p\mathbb{Z}$ is infinite. A ring homomorphism is lifted through G . A complex-linear map $T : V \rightarrow W$ has instead the explicitly defined $G(\mathbb{C})$ -linear lift $T^\tau(v^\bullet) = (Tv)^\bullet$, $T^\tau(\tau) = \tau$. In a support diagram the formula is $(\lambda, v) \mapsto (\varphi(\lambda), T_\lambda v)$, with its stated support map φ . These formulas commute with the respective amplitude observations.

Use exactly

$$\begin{aligned}
V &= \{\phi \in \mathcal{S}(\mathbb{R}) : \phi \text{ even}, \phi(0) = 0, \int_{\mathbb{R}} \phi = 0\}, \\
\mathcal{B} &= \{F \in C^\infty(\mathbb{R}_{>0}) : \sup_{x>0} x^b |D^j F(x)| < \infty \ (b \in \mathbb{Z}, j \geq 0)\}, \quad D = -x\partial_x, \\
C_+ &= [V \xrightarrow{\Theta} \mathcal{B}], \quad Q = \mathcal{B}/\Theta V, \quad \Theta\phi(x) = \sum_{n \neq 0} \phi(nx), \\
\phi_* &= (4\pi^2 x^4 - 6\pi x^2)e^{-\pi x^2}, \quad g(s) = 2\xi(s), \quad \mathcal{M}\Theta\phi = gH_\phi, \quad H_{\phi_*} = 1.
\end{aligned} \tag{1.2}$$

Let $h(s) = \prod_{\rho \in Z} (s - \rho)^{m_\rho}$ be a **nonempty** finite packet of actual zeros of g , with their full orders. Assume it is stable under $\rho \mapsto 1 - \bar{\rho}$. Put

$$d = \deg h, \quad v_h = g/h, \quad E_h = \mathbb{C}[s]/(h), \quad v_h = j_h(v_h) \in E_h^\times. \tag{1.3}$$

The preceding source provides the actual test function F_h and map

$$\begin{aligned}
\mathcal{M}F_h &= v_h, \quad h(D)F_h = \Theta\phi_*, \quad \mathcal{T}_h(P) = P(D)F_h, \\
\mathcal{T}_h(hP) &= \Theta(P(D)\phi_*), \quad J_h \mathcal{T}_h(P) = v_h[P]_h, \quad q\mathcal{T}_h(P) = \sigma_h(v_h[P]_h).
\end{aligned} \tag{1.4}$$

For $k \geq 2$, define

$$\begin{aligned}
\mathcal{P}_k &= \mathbb{C}[s_1, \dots, s_k], \quad I_k = (h(s_1), \dots, h(s_k)), \quad B_k = \mathcal{P}_k/I_k = E_h^{\otimes k}, \\
S &= s_1 + \dots + s_k, \quad A_k = M_S, \quad U_k = v_h^{\otimes k} \in B_k^\times.
\end{aligned} \tag{1.5}$$

The ordinary invariant submodule is $B_k^{\text{sym}} = B_k^{S_k}$. Its cochain realization is the existing signed chain projector $\frac{1}{k!} \sum_{\pi} \text{sgn}(\pi) T_\pi$: in top degree the Koszul sign in T_π cancels the displayed sign. The complementary cochain summand and both traces remain in the programme. No change to that projector is made here.

S13.1.2 2. The sum-generated submodule and its exact spectrum

Index the distinct roots by $\rho_1, \dots, \rho_a$, with orders $m_1, \dots, m_a$. For an occupation vector $\mathbf{n} = (n_1, \dots, n_a)$ with $\sum n_i = k$, set

$$\lambda_{\mathbf{n}} = \sum_i n_i \rho_i, \quad L_{\mathbf{n}} = 1 + \sum_i n_i (m_i - 1). \tag{2.1}$$

Let Λ_k be the set of distinct values of $\lambda_{\mathbf{n}}$, and put

$$\ell_\lambda = \max_{\mathbf{n}: \lambda_{\mathbf{n}} = \lambda} L_{\mathbf{n}}, \quad \chi_{h,k}(S) = \prod_{\lambda \in \Lambda_k} (S - \lambda)^{\ell_\lambda}. \tag{2.2}$$

Equal sums are grouped by their exact equality; no assumption of linear independence or of absent collisions is used. The distinct occupation idempotents stay in B_k^{sym} even when their sums agree.

Theorem 2.1. The polynomial (2.2) is the minimal polynomial of A_k both on B_k and on B_k^{sym} . There are an injective unital algebra map and a separate injective module map

$$\begin{aligned} \alpha_{h,k} : C_{h,k} &:= \mathbb{C}[S]/(\chi_{h,k}) \hookrightarrow B_k^{\text{sym}}, \quad [P] \mapsto P(A_k)1, \\ \eta_{h,k} = M_{U_k} \alpha_{h,k} : C_{h,k} &\hookrightarrow B_k^{\text{sym}}, \quad [P] \mapsto U_k P(A_k)1. \end{aligned} \quad (2.3)$$

The map M_{U_k} is an invertible B_k^{sym} -module map on its carrier. It is not asserted to be a unital algebra homomorphism; its inverse is $M_{U_k^{-1}}$. The full jet unit is retained by this pair of maps rather than assigned the value one.

Proof. At an ordered root tuple the local factor is

$$L_\rho = \mathbb{C}[z_1, \dots, z_k]/(z_1^{m_{i_1}}, \dots, z_k^{m_{i_k}}), \quad A_k = \lambda I + N, \quad N = M_{z_1 + \dots + z_k}.$$

Every monomial of degree greater than $\sum_j (m_{i_j} - 1)$ vanishes. In precisely that degree, $N^D 1$ contains the nonzero monomial $\prod z_j^{m_{i_j} - 1}$ with coefficient $D! / \prod (m_{i_j} - 1)!$. Thus its nilpotence index is $D + 1$. The minimal polynomial on the product takes the maximum index over factors at the same eigenvalue, which is (2.2). For the invariant algebra, the vector 1 is invariant and its annihilator under $\mathbb{C}[S]$ is already the same polynomial; indeed $P(A_k)1 = 0$ is equivalent to the algebra element $P(S)$ being zero. Thus restriction to invariants does not reduce this minimal polynomial. Multiplication by the actual unit U_k has zero kernel and commutes with A_k . This proves all assertions.

In particular, for every $\rho \in Z$, the value $k\rho$ occurs in Λ_k . The cyclic module has a nonzero eigenvector at every $\lambda \in \Lambda_k$: take the local class $(S - \lambda)^{\ell_\lambda - 1}$ in its Chinese-remainder factor, and zero in its other factors. Its image under $\eta_{h,k}$ is still nonzero and has eigenvalue λ .

This retains every exponent required for tensor amplification. It does not claim that a chosen repeated pure tensor is literally the same vector as this cyclic eigenvector when different occupations have the same sum. The original repeated-local-factor projection is the explicit map

$$C_{h,k} \xrightarrow{\eta_{h,k}} B_k^{\text{sym}} \longrightarrow L_{(\rho, \dots, \rho)}; \quad (2.4)$$

its complete nilpotent image is generated by the local unit times $1, N, \dots, N^{k(m_\rho - 1)}$. A cyclic eigenvector supported at a collided sum can have zero projection to a shorter local block. The spectral value is nevertheless present by the proved injection (2.3).

S13.1.3 The remainder of the arithmetic module remains as a quotient

Let

$$T_{h,k} = B_k^{\text{sym}} / \eta_{h,k} C_{h,k}.$$

Then

$$0 \rightarrow C_{h,k} \xrightarrow{\eta_{h,k}} B_k^{\text{sym}} \rightarrow T_{h,k} \rightarrow 0 \quad (2.5)$$

is an exact sequence of $\mathbb{C}[S]$ -modules. This is a module quotient, not a new algebra quotient of B_k . Its split lift is the original $G(\mathbb{C})$ -linear internal quotient. An element of the retained submodule maps to the supported zero; τ remains τ .

The sequence also has a constructed $\mathbb{C}[S]$ -linear retraction. On the generalized λ -part let $N_\lambda = A_k - \lambda I$, $w_\lambda = e_\lambda(A_k)U_k 1$, and $\ell = \ell_\lambda$. Choose the fixed-order root tuple attaining ℓ and let ϑ_λ extract

one of the top monomial coefficients of $N_\lambda^{\ell-1}w_\lambda$ there. That coefficient is its nonzero local arithmetic unit times the corresponding multinomial coefficient. In particular

$$\vartheta_\lambda(N_\lambda^{\ell-1}w_\lambda) \neq 0.$$

Define

$$\pi_\lambda^0(v) = \sum_{j=0}^{\ell-1} \vartheta_\lambda(N_\lambda^{\ell-1-j}v)X^j \pmod{X^\ell}, \quad p_\lambda(X) = \pi_\lambda^0(w_\lambda).$$

Its constant term is nonzero, so p_λ has a unique multiplicative inverse modulo X^ℓ . The actual retraction is

$$\boxed{\pi_\lambda(v) = p_\lambda(X)^{-1}\pi_\lambda^0(v)}. \quad (2.5a)$$

Indeed $\pi_\lambda^0(N_\lambda v) = X\pi_\lambda^0(v)$, and $\pi_\lambda(w_\lambda) = 1$. Combining these maps with the CRT idempotents gives $\pi : B_k^{\text{sym}} \rightarrow C_{h,k}$ with $\pi\eta_{h,k} = 1$. Thus the inverse pair is

$$\begin{aligned} C_{h,k} \oplus \ker \pi &\longrightarrow B_k^{\text{sym}}, & (c, t) &\mapsto \eta_{h,k}c + t, \\ v &\longmapsto (\pi v, v - \eta_{h,k}\pi v). \end{aligned} \quad (2.5b)$$

The quotient $T_{h,k}$ is linked to $\ker \pi$ by $[v] \mapsto v - \eta\pi v$, with inverse given by inclusion followed by the quotient. This retains every remaining nilpotent block; at each sum precisely one maximal-length block is assigned to the cyclic summand. The choice of top coefficient is recorded. This splitting is not asserted orthogonal: an arithmetic Gram H pulls back to the full block matrix containing $\eta^*H\eta$, $\eta^*H|_{\ker \pi}$, and its adjoint cross term, not just their diagonal blocks.

On a fixed sum λ , the dimension of the symmetric generalized eigenspace is

$$a_\lambda = \sum_{\mathbf{n}:\lambda_{\mathbf{n}}=\lambda} \prod_i \binom{n_i + m_i - 1}{m_i - 1}. \quad (2.6)$$

Thus $T_{h,k}$ has dimension $a_\lambda - \ell_\lambda$ there. For every entire f , trace additivity in (2.5) proves

$$\text{Tr}(f(A_k)|B_k^{\text{sym}}) = \sum_\lambda \ell_\lambda f(\lambda) + \sum_\lambda (a_\lambda - \ell_\lambda) f(\lambda). \quad (2.7)$$

The first term is the cyclic trace; the second is the retained quotient trace. All terms get the same cohomological factor $(-1)^k$ in top-degree supertrace. This calculation is valid with nilpotents; it does not replace their modules by their residue values.

For example, the algebraic fixture with simple roots $1/4, 1/2, 3/4$ and $k = 2$ has a six-dimensional symmetric module but a five-dimensional cyclic module. The two occupations with sum 1 give a one-dimensional quotient at that sum. The fixture with one root of order three and $k = 2$ has symmetric dimension six, cyclic length five, and quotient length one at 2ρ . These are fixtures of the formulas, not assertions of zeta zeros at those locations or multiplicities.

S13.1.4 3. An original source realization whose norm is the scalar sum density

Define the linear map

$$\boxed{\mathcal{V}_{h,k} : \mathbb{C}[S] \rightarrow \mathcal{B}^{\otimes k}, \quad P \mapsto P(D_1 + \cdots + D_k)(F_h^{\otimes k})}. \quad (3.1)$$

Its Mellin transform is

$$\mathcal{M}^{(k)}\mathcal{V}_{h,k}(P) = \left(\prod_i v_h(s_i) \right) P(s_1 + \cdots + s_k).$$

It is injective: if this analytic function vanishes, it vanishes on an open set where all v_h are nonzero, forcing the polynomial P to vanish identically. Its actual arithmetic map is

$$\boxed{J^{(k)}\mathcal{V}_{h,k} = \eta_{h,k}\pi_\chi, \quad q^{(k)}\mathcal{V}_{h,k} = \sigma_h^{\otimes k}\eta_{h,k}\pi_\chi,} \quad (3.2)$$

where $\pi_\chi(P) = [P]_\chi$. Thus its arithmetic kernel is exactly (χ) and not a selected subset of the original relations.

Let $q_k = \deg \chi_{h,k}$ and $N \geq q_k - 1$. At finite source degree,

$$\boxed{0 \rightarrow \mathbb{C}[S]_{\leq N-q_k} \xrightarrow{\times \chi} \mathbb{C}[S]_{\leq N} \xrightarrow{\pi_\chi} C_{h,k} \rightarrow 0.} \quad (3.3)$$

A negative bound means the zero space. Define the actual boundary space

$$\mathcal{D}_{h,k,N} = \mathcal{V}_{h,k}(\chi \mathbb{C}[S]_{\leq N-q_k}).$$

Because $\chi(s_1 + \cdots + s_k) \in I_k$, fixed-order monic division gives

$$\chi(S)Q(S) = \sum_i h(s_i)Q_i(\mathbf{s}). \quad (3.4)$$

Each term is an original top cochain boundary: replace F_h in factor i by ϕ_* , apply the polynomial $Q_i(D_1, \dots, D_k)$, and give the primitive $(-1)^{i-1}$. The tensor differential gives the second $(-1)^{i-1}$. Their product is $+1$. This supplies the original primitive rather than defining a new vanishing relation by fiat.

The split quotient of (3.3) has equality criterion $P \sim P'$ precisely when $P - P' \in \chi \mathbb{C}[S]_{\leq N-q_k}$. A relation maps to the supported zero at label λ_N . Degree transport retains the preceding label and its killed-representative kernel.

S13.1.5 The exact norm

Retain from [S1]

$$a_h(t) = \frac{v_h(1/2 + it)}{\sqrt{2\pi}}, \quad w_h(t) = |a_h(t)|^2, \quad \mu_h = \int w_h, \quad m_{h,k} = w_h^{*k}.$$

In centered sum coordinates $u = \sum t_i$, $y_i = t_i - u/k$, the amplitude is $\Psi_{h,k}(u, \mathbf{y}) = \prod_i a_h(u/k + y_i)$. Its relative integral is $m_{h,k}(u)$. Therefore

$$\boxed{\|\mathcal{V}_{h,k}P\|_{L^2(d^k x)}^2 = \int_{\mathbb{R}} |P(k/2 + iu)|^2 m_{h,k}(u) du.} \quad (3.5)$$

This is the restriction of the preceding full matrix-weight realization to the **specific source family** $P(S)$, through (3.1) and (3.2). It does not identify every relative coefficient with the constant relative coefficient.

The full relative module remains in (2.5). For comparison with the previous least-norm representative, at the same ambient degree N the maps obey

$$\mathcal{V}_{h,k}(\mathbb{C}[S]_{\leq N}) \hookrightarrow \mathcal{T}_h^{(k)}(\mathcal{P}_{k,N}), \quad \mathcal{D}_{h,k,N} \hookrightarrow \mathcal{B}_{k,N}.$$

Let $R_{k,N}^{\text{full}}$ be the old joint minimum, and $\mathcal{R}_N$ the cyclic minimum constructed next. Their exact relationship is

$$\Delta_N = \mathcal{R}_N - R_{k,N}^{\text{full}} \eta_{h,k} \in \text{Hom}(C_{h,k}, \mathcal{B}_{k,N}),$$

$$\boxed{\mathcal{G}_N = \eta_{h,k}^* G_{k,N}^{\text{full}} \eta_{h,k} + \Delta_N^* \Delta_N.} \quad (3.6)$$

Both maps represent the same full jets; their difference is in the original relation ideal, and the full minimum is orthogonal to it. This proves (3.6). The corresponding control difference is

$$\mathcal{W}_N - \eta_{h,k}^* W_{k,N}^{\text{full}} \eta_{h,k} = A_\chi^* \Delta_N^* \Delta_N + \Delta_N^* \Delta_N A_\chi - k \Delta_N^* \Delta_N. \quad (3.7)$$

This explicitly retains why the Gram inequality does not itself order the control forms.

The scalar source must reach degree $q_k - 1$ to realize all cyclic jets. This can exceed $k(d - 1)$. The reduction in relative rank has a degree cost which remains in every estimate.

S13.1.6 4. Canonical scalar representatives and rank-two arithmetic control

Apply Gram-Schmidt by subtracting lower-degree projections from $1, S, S^2, \dots$ for the exact measure in (3.5). Let $p_j^{[h,k]}$ be the resulting polynomial with leading coefficient one, and retain

$$\omega_j^{[h,k]} = \int |p_j^{[h,k]}(k/2 + iu)|^2 m_{h,k}(u) du > 0. \quad (4.1)$$

No polynomial is divided by its norm. In particular $\omega_0^{[h,k]} = \mu_h^k$. For this section suppress the indices h, k and write

$$b_j = [p_j]_\chi \in C_{h,k}, \quad \mathcal{K}_N = \sum_{j=0}^N \frac{b_j b_j^*}{\omega_j}, \quad \mathcal{G}_N = \mathcal{K}_N^{-1}. \quad (4.2)$$

The coordinates on $C_{h,k}$ are the fixed remainder basis $1, S, \dots, S^{q_k-1}$. Its inclusion into the original full jets is $\eta_{h,k}$, carrying U_k ; b_j is not an assertion that $U_k = 1$.

The unique least-norm representative modulo the specified $\mathcal{D}_{h,k,N}$ is

$$\boxed{\mathcal{R}_N u = \mathcal{V}_{h,k} \left(\sum_{j=0}^N p_j \frac{b_j^* \mathcal{G}_N u}{\omega_j} \right).} \quad (4.3)$$

Its identities are

$$J^{(k)} \mathcal{R}_N = \eta_{h,k}, \quad q^{(k)} \mathcal{R}_N = \sigma_h^{\otimes k} \eta_{h,k}, \quad \mathcal{R}_N^* \mathcal{R}_N = \mathcal{G}_N. \quad (4.4)$$

Proof. The coefficient map in (4.3) is the weighted adjoint of the full remainder map followed by $(JJ^*)^{-1}$ in the displayed orthogonal coordinates. Multiplication verifies its right-inverse identity. If Z is another polynomial with the same remainder, their difference lies in the exact kernel (3.3); the cross term with (4.3) is zero by the adjoint formula. The norm is therefore the displayed minimum plus the squared norm of that difference. This proves uniqueness and all equations, before any completion of the arithmetic quotient.

Let $A_\chi = M_S$ on $C_{h,k}$. Multiplication by S has adjoint multiplication by $k - S$ on the integration line. Orthogonality and leading coefficients give

$$Sp_j = p_{j+1} + \beta_j p_j - \frac{\omega_j}{\omega_{j-1}} p_{j-1}, \quad \Re \beta_j = k/2, \quad (4.5)$$

with the last term absent at $j = 0$. This is the ordinary orthogonal-polynomial recurrence in the retained complex coordinate; its general framework is recorded in DLMF §18.2 [E1].

Theorem 4.1 (two-row control on a spectrum-complete submodule).

$$\mathcal{Z}_N := A_\chi \mathcal{K}_N + \mathcal{K}_N A_\chi^* - k \mathcal{K}_N = \frac{b_{N+1} b_N^* + b_N b_{N+1}^*}{\omega_N}. \quad (4.6)$$

Consequently

$$\mathcal{W}_N := A_\chi^* \mathcal{G}_N + \mathcal{G}_N A_\chi - k \mathcal{G}_N = \mathcal{G}_N \mathcal{Z}_N \mathcal{G}_N, \quad \text{rank } \mathcal{W}_N \leq 2. \quad (4.7)$$

Proof. Substitute (4.5) into the finite sum (4.2). Each adjacent pair internal to $0, \dots, N$ cancels because the negative lower coefficient is exactly $-\omega_j/\omega_{j-1}$. Each diagonal pair is $k b_j b_j^*/\omega_j$. The only remaining adjacent pair is the one in (4.6). Congruence gives (4.7). This is a Christoffel–Darboux cancellation on the actual cyclic source, not a statement that the full relative module’s control has rank two.

S13.1.7 The original next relation is retained

Define

$$\mathfrak{b}_N = \mathcal{V}_{h,k}(p_{N+1}) - \mathcal{R}_N b_{N+1}.$$

Its full jets vanish and its polynomial degree is $N + 1$. It gives the explicit isomorphism

$$\mathbb{C} \xrightarrow{c \mapsto c \mathfrak{b}_N} \mathcal{D}_{h,k,N+1} \cap \mathcal{D}_{h,k,N}^\perp \xrightarrow{z \mapsto [z]} \mathcal{D}_{h,k,N+1} / \mathcal{D}_{h,k,N}. \quad (4.8)$$

The leading term proves injectivity; the one-dimensional degree increment proves surjectivity. Its norm and pairing are

$$\|\mathfrak{b}_N\|^2 = \omega_{N+1} + b_{N+1}^* \mathcal{G}_N b_{N+1}, \quad \mathfrak{b}_N^* \mathcal{R}_N = -b_{N+1}^* \mathcal{G}_N. \quad (4.9)$$

The class is nonzero at degree N and becomes the receiving supported zero at degree $N + 1$. Its theta primitive is obtained from the original division (3.4). The scalar support itself is not adjoined again.

The exact update is

$$\begin{aligned} \mathcal{K}_{N+1} &= \mathcal{K}_N + b_{N+1} b_{N+1}^* / \omega_{N+1}, \\ \mathcal{G}_{N+1} &= \mathcal{G}_N - \frac{\mathcal{G}_N b_{N+1} b_{N+1}^* \mathcal{G}_N}{\omega_{N+1} + b_{N+1}^* \mathcal{G}_N b_{N+1}}. \end{aligned} \quad (4.10)$$

S13.1.8 Same-metric reflection and exact excess

Let $P^{\dagger k}(S) = \overline{P(k - \bar{S})}$. The polynomial χ obeys $\chi^{\dagger k} = (-1)^{q_k} \chi$. The induced antilinear involution on the **weighted** cyclic module is

$$j_C[P] = (-1)^{kd} [P^{\dagger k}]. \quad (4.11)$$

This sign is forced by $U_k^\dagger = (-1)^{kd}U_k$ in the original embedding. It intertwines with the actual function reflection and preserves the source degree and norm. Hence the unique minimum obeys reflection on the same $\mathcal{G}_N$.

Uniqueness of the monic orthogonal polynomial gives $p_j^{\dagger k} = (-1)^j p_j$. In particular

$$c_N = b_N^* \mathcal{G}_N b_{N+1} \quad \text{satisfies} \quad \bar{c}_N = -c_N.$$

Write $a_N = b_N^* \mathcal{G}_N b_N$ and $d_N = b_{N+1}^* \mathcal{G}_N b_{N+1}$. The nonzero generalized control eigenvalues are the eigenvalues of

$$\frac{1}{\omega_N} \begin{pmatrix} \bar{c}_N & d_N \\ a_N & c_N \end{pmatrix}.$$

Therefore the exact least two-sided excess is

$$\epsilon_{h,k,N}^{\text{cyc}} = \frac{\sqrt{a_N d_N - |c_N|^2}}{\omega_N}. \quad (4.12)$$

The determinant is nonnegative by the Gram inequality. Zero and rank-one degeneracies are covered by the same formula; in the reflection-stable case a nonzero rank-one signed defect cannot occur. No phase is dropped.

For the actual eigenvector at $k\rho$ constructed in Section 2,

$$k|2\Re\rho - 1| \leq \epsilon_{h,k,N}^{\text{cyc}}. \quad (4.13)$$

This is a proved diagnostic of this explicit family. A sublinear bound on the calculated right side as k grows is still to be established from the arithmetic input. The rank-two identity is not such a bound by itself.

S13.1.9 5. Keep packet changes through their actual source seeds

Let $h \mid H$ include complete multiplicities, and let $m = H/h$. Then

$$F_h = m(D)F_H, \quad \mathcal{V}_{h,k}P = \mathcal{T}_H^{(k)} \left(\prod_i m(s_i) P(S) \right). \quad (5.1)$$

The full CRT inclusion on jets is the $\mathbb{C}[S]$ -linear map which inserts zero jets at the added centres. Its old unit maps to the associated idempotent, so it is not described as a unital algebra inclusion into the entire larger packet.

The right side of (5.1) has the fixed seed $a_{hH}(\mathbf{s}) = \prod_i m(s_i)$. Its source norm is exactly the old norm, since $(g/H)m = g/h$ in every factor. It therefore defines an isometric map of the marked polynomial sources and their internal quotients, with the old cyclic annihilator $\chi_{h,k}$.

This is the correct packet-coherence comparison. The new seed is generally not a polynomial in S alone. For example, if $m(s) = s - 1/2$ and $k = 2$, then

$$m(s_1)m(s_2) = \frac{(S-1)^2 - (s_1 - s_2)^2}{4}. \quad (5.2)$$

The relative square and its coefficient are retained. The explicit source-seed map (5.1), followed by the larger packet's full relative source inclusion, replaces any unjustified identification with that larger packet's unmarked constant-seed cyclic submodule. No original packet, supported relation, or canonical scalar norm is changed by this marked comparison.

S13.1.10 6. The scalar Fisher estimate now acts on this source, and all polynomial derivative moments are calculable

From [S1],

$$\mathcal{I}_{h,k} + 4 \int \|n_{h,k}(u)\|^2 du = \frac{\mu_h^{k-1}}{k} \mathcal{I}_h, \quad \mathcal{I}_h = 4 \int |a'_h(t)|^2 dt. \quad (6.1)$$

The cyclic source (3.5) uses **that very density** $m_{h,k}$, not another scalar replacement for the full matrix norm. The full derivative still has the specified two components:

$$\partial_u(\Psi_{h,k}P(k/2 + iu)) = \Psi_{h,k} \left(iP'(k/2 + iu) + \frac{m'_{h,k}}{2m_{h,k}} P(k/2 + iu) \right) + n_{h,k}P(k/2 + iu). \quad (6.2)$$

They are pointwise orthogonal. The second component is retained even though the original coefficient polynomial depends only on the sum. Its arithmetic interpretation is the graph map and logarithmic observable from [S1]. The generator remains A_k ; the derivative corresponds to $i\mathcal{L}_k$, with $[D^{(k)}, \mathcal{L}_k] = -1$.

S13.1.11 Raw moments give the complete differentiated finite source without multidimensional quadrature

Define the finite moments

$$\mu_j = \int t^j |a_h(t)|^2 dt, \quad \nu_j = \int t^j |a'_h(t)|^2 dt, \quad \theta_j = \int t^j \overline{a_h(t)} a'_h(t) dt.$$

Fixed arithmetic phase and integration by parts give

$$\theta_0 = 0, \quad \theta_j = -\frac{j}{2} \mu_{j-1} \quad (j \geq 1). \quad (6.3)$$

Use the **formal** exponential generating series

$$\mathcal{M}(z) = \sum_{j \geq 0} \mu_j z^j / j!, \quad \mathcal{N}(z) = \sum_{j \geq 0} \nu_j z^j / j!.$$

No convergence of these series is needed for the finite coefficient identities. Their constant terms remain the actual mass and derivative energy.

Let

$$M_{j,k} = \int u^j m_{h,k}(u) du, \quad B_{j,k} = \int u^j \|\partial_u \Psi_{h,k}(u, \cdot)\|^2 du.$$

Theorem 6.1 (all polynomial derivative moments).

$$M_{j,k} = j! [z^j] \mathcal{M}(z)^k, \quad (6.4)$$

$$B_{j,k} = j! [z^j] \left[\frac{1}{k} \mathcal{N}(z) \mathcal{M}(z)^{k-1} + \frac{k-1}{4k} z^2 \mathcal{M}(z)^k \right]. \quad (6.5)$$

Proof. Expand $u^j = (t_1 + \cdots + t_k)^j$ and use Fubini; all integrals are absolutely finite. For (6.5), the diagonal terms of $|k^{-1} \sum_i a'_i \prod_{r \neq i} a_r|^2$ give $k^{-1} \mathcal{N} \mathcal{M}^{k-1}$. The distinct-index terms give

$(k-1)\Theta(z)^2\mathcal{M}^{k-2}/k$, where $\Theta(z) = \sum \theta_j z^j/j! = -z\mathcal{M}(z)/2$ by (6.3). Substitution gives the displayed expression. The second term is not discarded: the cross terms vanish only for the unweighted zeroth moment, not for arbitrary polynomial moments.

In particular,

$$\begin{aligned} M_{0,k} &= \mu_0^k, & M_{1,k} &= k\mu_1\mu_0^{k-1}, \\ M_{2,k} &= k\mu_2\mu_0^{k-1} + k(k-1)\mu_1^2\mu_0^{k-2}, \\ B_{0,k} &= \frac{1}{k}\nu_0\mu_0^{k-1} = \frac{\mu_h^{k-1}}{4k}\mathcal{I}_h. \end{aligned} \quad (6.6)$$

The first orthogonal norm and diagonal coefficient on the sum line are accordingly

$$\omega_0 = \mu_0^k, \quad \beta_0 = \frac{k}{2} + i\frac{k\mu_1}{\mu_0}, \quad \omega_1 = k\mu_0^{k-2}(\mu_0\mu_2 - \mu_1^2). \quad (6.7)$$

No symmetry assumption setting $\mu_1 = 0$ is made.

For any two polynomials P, Q , let $c_P(u) = P(k/2 + iu)$ and $c_Q(u) = Q(k/2 + iu)$. Their complete graph-energy form is

$$\begin{aligned} \mathfrak{D}_k(P, Q) &= \int \overline{c_P}c_Q \|\Psi'_k\|^2 du + \int \overline{c'_P}c'_Q m_k du \\ &\quad + \frac{1}{2} \int \left(\overline{c_P}c'_Q + \overline{c'_P}c_Q \right) m'_k du. \end{aligned} \quad (6.8)$$

All four terms remain. Equations (6.4)–(6.5) and $\frac{1}{2} \int u^j m'_k = -jM_{j-1,k}/2$ evaluate every matrix entry on a fixed polynomial degree using only μ_j, ν_j . This is the complete derivative graph norm from the existing sum-fibre construction, not merely the scalar score norm. It is positive definite on every nonzero polynomial source: a zero derivative would make $\Psi_k P$ constant in u for almost every relative coordinate, while its decay forces that constant and then P to be zero.

For a finite canonical representative, its graph-energy matrix is obtained by applying its actual coefficient matrix from (4.3) on both sides of (6.8). Thus there are now explicit moment matrices for both the original metric and the differentiated representative. No continuous jet functional on arbitrary L^2 classes is assumed.

S13.1.12 7. Exact sum-coordinate conormal depth at every original thickening

The derivative graph still needs the class **before** an original relation is sent to e . The required domains can now be computed exactly on the sum line.

For $r \geq 1$, retain the original thickened ring

$$B_{k,r} = \mathcal{P}_k/I_k^r.$$

Define, for an ordered root tuple $\rho = (\rho_{i_1}, \dots, \rho_{i_k})$,

$$\begin{aligned} L_{\rho,r} &= 1 + \sum_{j=1}^k (m_{i_j} - 1) + (r-1) \max_j m_{i_j}, \\ \ell_{\lambda,r} &= \max_{\rho: \sum \rho_{i_j} = \lambda} L_{\rho,r}, \quad \boxed{\chi_{h,k,r}(S) = \prod_{\lambda \in \Lambda_k} (S - \lambda)^{\ell_{\lambda,r}}}. \end{aligned} \quad (7.1)$$

Theorem 7.1. The exact contracted ideal is

$$\boxed{I_k^r \cap \mathbb{C}[S] = (\chi_{h,k,r}).} \quad (7.2)$$

Consequently there is an injective unital algebra map

$$\boxed{\alpha_r : C_{h,k,r} := \mathbb{C}[S]/(\chi_{h,k,r}) \hookrightarrow B_{k,r}^{S_k}, \quad [P] \mapsto [P(S)].} \quad (7.3)$$

Proof. At a root tuple, the units in $h(\rho_i + z_i) = u_i(z_i)z_i^{m_i}$ make the original local ideal equal to $(z_1^{m_1}, \dots, z_k^{m_k})$, with its r th power retained. A monomial z^α survives precisely when

$$\sum_i \left\lfloor \frac{\alpha_i}{m_i} \right\rfloor \leq r - 1. \quad (7.4)$$

The largest surviving total degree is $\sum_i (m_i - 1) + (r - 1) \max_i m_i$. It is attained by assigning all $r - 1$ full blocks to an index of maximal m_i , and taking remainders $m_i - 1$ in every index. The corresponding term of $(\sum z_i)^D$ has coefficient $D! / \prod \alpha_i! \neq 0$. All terms of degree $D + 1$ vanish. Thus the exact nilpotence index is (7.1). Take the maximum over collided sums and then the product over different sums. This gives precisely the annihilator of the algebra element S , proving (7.2). The same cyclic image is in the invariants because S and 1 are invariant. No local unit has been discarded: it enters the specified invertible change of generators of the ideal, not an alteration of the physical coordinate S .

S13.1.13 Quotient and derivative maps on the same tower

There are commuting quotient squares

$$\begin{array}{ccc} C_{h,k,r+1} & \xrightarrow{\alpha_{r+1}} & B_{k,r+1} \\ \downarrow & & \downarrow \\ C_{h,k,r} & \xrightarrow{\alpha_r} & B_{k,r}. \end{array} \quad (7.5)$$

Each quotient is a ring map, hence has the original split lift. Its kernel is retained. On the sum side,

$$0 \rightarrow \mathbb{C}[S]/(\chi_{r+1}/\chi_r) \xrightarrow{\times \chi_r} C_{r+1} \rightarrow C_r \rightarrow 0. \quad (7.6)$$

The first arrow is explicitly a module map. Under α_{r+1} its image lies in I_k^r/I_k^{r+1} ; this is the actual relation fibre sent to the supported zero by the right vertical quotient.

The exact exponent satisfies $\ell_{\lambda,r+1} \geq \ell_{\lambda,r} + 1$. Hence χ_r divides χ'_{r+1} , and the linear derivative map is well-defined:

$$\boxed{\partial_r : C_{r+1} \rightarrow C_r, \quad [P] \mapsto [P']}. \quad (7.7)$$

It commutes with the original relative-sum derivative

$$\delta_r : B_{k,r+1} \rightarrow B_{k,r}, \quad [P] \mapsto \left[\frac{1}{k} \sum_i \partial_{s_i} P \right],$$

$$\boxed{\delta_r \alpha_{r+1} = \alpha_r \partial_r.} \quad (7.8)$$

The derivatives are coefficient-linear maps and are lifted as such, not called ring homomorphisms. For example,

$$h(s) = (s - \rho)^2, \quad k = 2, \quad X = S - 2\rho \implies \chi_r = X^{2r+1}. \quad (7.9)$$

The class X^3 is nonzero modulo X^5 , maps to the supported zero modulo X^3 , and its derivative maps to $3X^2$, which is nonzero there.

This also calculates the relationship to a naive scalar power thickening:

$$\mathbb{C}[S]/(\chi_1^r) \twoheadrightarrow C_r \hookrightarrow B_{k,r}. \quad (7.10)$$

For the fixture in (7.9) at $r = 2$, the first map is $\mathbb{C}[X]/(X^6) \twoheadrightarrow \mathbb{C}[X]/(X^5)$, with kernel the retained class of X^5 . The original joint thickening therefore carries a different sum-coordinate depth, and the precise quotient above gives their relationship. This is a calculation about powers of the original relation ideal; it is not iteration of the scalar zero adjunction.

S13.1.14 The arithmetic Taylor unit remains through differentiation

Let $U_{k,r}$ be the full Taylor class of $\prod v_h(s_i)$ in $B_{k,r}$. It is invertible and compatible under the quotient tower. Define the coefficient-linear inclusion

$$\eta_r = M_{U_{k,r}} \alpha_r.$$

The full equation is

$$\boxed{\delta_r \eta_{r+1}(P) = U_{k,r} \alpha_r(P') + (\delta_r U_{k,r+1}) \alpha_r(P).} \quad (7.11)$$

The second term remains in the relative ring $B_{k,r}$. It is not presumed to be in the cyclic image. Its exact map is $M_{\delta_r U_{k,r+1}} \alpha_r$, and the complementary quotient $B_{k,r}/\eta_r C_r$ records its noncyclic part. This is the algebraic counterpart of the retained normal derivative in (6.2).

At $r = 1$, the quotient and derivative thus give two actual maps out of the same lifted thickening. A conormal relation can map to e under the quotient and to a nonzero supported value under the derivative. Differentiating the original theta relation, not the scalar e itself, is what produces that value.

S13.1.15 8. The conormal derivative reaches both cyclic and full arithmetic traces, with their difference retained

Choose an original division

$$\chi_1(S) = \sum_i h(s_i) B_i(\mathbf{s}).$$

Applying the actual derivative and then the original quotient yields

$$\boxed{\alpha_1(\chi_1') = \frac{1}{k} \sum_i h'(s_i) [B_i]_{I_k}.} \quad (8.1)$$

The right side is the source's conormal row. For the weighted relation $U \chi_1 P$, the term containing δU has an undifferentiated χ_1 and vanishes in B_k . Therefore

$$\boxed{\delta_1[U \chi_1 P]_{I_k^2} = U_k \alpha_1(\chi_1' P).} \quad (8.2)$$

It has the actual analytic representative

$$J^{(k)} \mathcal{L}_k \mathcal{V}_{h,k}(\chi_1 P) = U_k \alpha_1(\chi'_1 P), \quad \mathcal{L}_k = \frac{1}{k} \sum_i \log x_i. \quad (8.3)$$

Here the left source is an original theta boundary, supplied by (3.4). Its first differentiated arithmetic value is read before it is collapsed to its supported zero.

For $C_1 = \mathbb{C}[S]/(\chi_1)$, the explicitly chosen finite residue pairing is

$$R_\chi(f, P) = \sum_\lambda \text{Res}_{S=\lambda} \frac{f^{\dagger k}(S) P(S)}{\chi_1(S)} dS.$$

Its Jacobian contraction is

$$R_\chi(f, \chi'_1 P) = \sum_\lambda \ell_\lambda \overline{f(k - \bar{\lambda})} P(\lambda) = \text{Tr}(M_{f^{\dagger k} P} | C_1). \quad (8.4)$$

This is the cyclic trace. The original full symmetric trace has a_λ instead of ℓ_λ and is their sum with the quotient trace (2.7). Equivalently, let $\chi_{\text{full}}(S) = \prod_\lambda (S - \lambda)^{a_\lambda}$. Its difference is the explicit residue functional

$$\text{Tr}(f(A_k) | T_{h,k}) = \sum_\lambda \text{Res}_{S=\lambda} f(S) \left(\frac{\chi'_{\text{full}}}{\chi_{\text{full}}} - \frac{\chi'_1}{\chi_1} \right) dS. \quad (8.5)$$

There is a further explicit comparison for the original arithmetic vector pairing. Its pullback through the **weighted** inclusion is

$$\text{Tr}_{B_k^{\text{sym}}} M_{(\eta f)^{\dagger} \eta P} = \text{Tr}_{B_k^{\text{sym}}} M_{U_k^{\dagger} U_k \alpha_1(f^{\dagger k} P)}. \quad (8.6)$$

The factor $U_k^{\dagger} U_k$ remains. It need not lie in the sum-generated subalgebra. The trace decomposition (2.7) applies to the invariant operator $f(A_k)$; it is not an assertion that this weighted vector pairing is automatically the cyclic residue form (8.4).

Neither polynomial is substituted for the original $g = 2\xi$. Their finite trace comparison is (8.5), while $U_{k,r}$ and the map (8.3) retain their arithmetic source. The original product residue/Jacobian trace can still be evaluated on the full module and its retained quotient. No trace contribution is declared absent.

S13.1.16 9. Checks, counterfactual tests, and the next estimate

The exact checker implements finite polynomial, matrix, and Gaussian-amplitude fixtures. Its tests cover exact thickening dimensions and nilpotence; collision grouping; cyclic injections and trace complements; the non-naive thickening map; the derivative square; supported-zero versus absence; the original conormal row; full unit differentiation; scalar minimum and updates; rank-two control; reflection with a nonzero imaginary cross term; amplified off-line test exponents; raw convolution and complete polynomial derivative moments; and the marked source-seed transition. These are regression checks, not tests asserting that a fixture's roots are zeta zeros.

In particular an off-line reflected polynomial fixture remains off-line under the new construction: its exact eigenline identity is still $2\Re\lambda - k$. The scalar Fisher contraction does not annul this value. This guards against an inference from convolution smoothing alone to purity. The constructive object supplied instead is (4.12): two explicitly computed full-jet rows relative to the exact cyclic interpolation metric, with every scalar moment obtainable from the original one-factor moments by (6.4).

The degree cost $N \geq \deg \chi_{h,k} - 1$ and the reciprocal metric in (4.12) are retained as k grows. The derivative matrix (6.8) likewise keeps the polynomially weighted normal contribution. Controlling those quantities on the actual arithmetic inputs, rather than just the constant polynomial, is the remaining quantitative step of this branch.

The connection to the Deligne amplification programme is now a smaller, exactly included cohomological image with every amplified exponent represented; its source norm is the scalar sum-density norm for which (6.1) was proved. The original multi-direction module, its complementary trace, and all powers of its conormal ideal remain as explicit surrounding objects. This is not a transfer of finite-field purity by notation.

No remote repository is modified in this delivery. The user has assigned GitHub integration and Lean work to the parallel session. The authored note, checker, and a bounded handoff are ready for that session without changes to its existing files.

S14 Exterior trace amplification with the original arithmetic Gram and full quartet multiplicities

Source attribution. Complete TeX witness supplied in the Exterior Trace Amplification archive. The original Gram, additive exterior action, factorial tensor inclusion, full generalized eigenspaces and quartet multiplicities are retained. The source supplies an amplification lower bound and explicitly leaves the actual subcubic arithmetic upper estimate unproved. Its finite fixtures and source-reported verification have their recorded scopes; the separate PR 21 formalization is identified independently.

S14.1 Result and scope

The previous cyclic-sum construction has a Hermitian control form of rank at most two. The continuation here uses that specific property, rather than changing its metric. Passing to an exterior power of the same arithmetic module does **not** multiply the control allowance by the exterior degree. It makes it possible to control a determinant line containing the sum of the positive real-part defects.

For the actual cyclic packet and its specified least-norm representative, the new inequality is

$$\sum_{\Re \lambda > k/2} \ell_{\lambda}(2\Re \lambda - k) \leq \epsilon_{h,k,N}^{\text{cyc}}.$$

For a complete nonreal off-line quartet with real displacement $\delta > 0$ and common multiplicity m , it gives the exact lower bound

$$\epsilon_{h,k,N}^{\text{cyc}} \geq 2\delta [1 + k(m-1)](k+1) \left\lfloor \frac{(k+1)^2}{4} \right\rfloor, \quad N \geq [1 + k(m-1)](k+1)^2 - 1.$$

For simple roots this grows as $\delta k^3/2$. The corresponding sufficient analytic target is therefore a **subcubic** upper bound on this same explicitly defined allowance, rather than the earlier sublinear target obtained from one repeated eigenvector. This note proves the lower bound and constructs the exterior/cohomological maps. It does not prove that analytic upper bound, and it does not claim RH.

The finite-dimensional extremal-trace ingredient is classical: it is a rank-two case of the Ky Fan principle. The contribution here is its application through the existing arithmetic representatives, their original theta boundaries, their split-support lifts, and the exact sum-set and multiplicity calculation. General finite-dimensional linear algebra is not presented as a new classical theorem.

S14.2 1. GitHub corrections integrated at a pinned revision

The repository read for this continuation is KokunoYumeto/zeta-function-research-reader, with pinned main revision

a4494fba4968db837a8af6fcb952c8688cd5d1da.

The inspection was bounded: the latest PR metadata, the main revision, the current sum-connection note, selected parts of the new Stieltjes/conormal continuation, and the formal frontier note. It was not an independent audit of the entire 292-page edition.

S14.2.1 1.1 The empty packet

The current PR #20 source explicitly corrects the scope of its monic-freeness argument. For a nonempty packet $d = \deg h \geq 1$, the original conormal calculation applies. For $h = 1$ and $k \geq 2$,

$$I = (h(s_1), \dots, h(s_k)) = \mathbb{C}[s_1, \dots, s_k], \quad \mathbb{C}[\mathbf{s}]/I^r = 0 \quad (r \geq 1).$$

The algebraic spectral module is then zero. Its split lift $G(0)$ still contains the external absence τ and the supported zero e . The analytic amplitude g and its mass do not vanish. No Gram inverse on a nonzero spectral space is inferred from that analytic amplitude.

Every inverse matrix below is on a **nonempty** actual spectral packet. The empty case has the unique maps between zero coefficient modules and the corresponding original split lifts.

The reviewed public note blob is 797d8bc298aec06b112b53a03654a9664323e748. Its historical validation file records an earlier note blob; that historical receipt is not relabelled as a new proof check.

S14.2.2 1.2 Metric restriction retains its hypotheses

The current formal frontier note requires, for rectangular inclusion and extraction matrices,

$$LI = 1, \quad P = IL = P^*, \quad PK = KP, \quad GK = 1$$

before concluding

$$(I^*GI)(LKL^*) = 1.$$

The spectral projection used later need not be orthogonal for the arithmetic metric. Accordingly this note uses the actual compressed Gram $C_+^*GC_+$ and its inverse. It does not replace that inverse by $C_+^*G^{-1}C_+$.

S14.2.3 1.3 Formalization and source boundaries

The source library already constructs the original internal quotient, cohomology maps, comparison kernels, support-changing morphisms, and homology of a cochain-idempotent image. These are inputs. This continuation neither reruns Lean nor extends the scope of their published certificates to the analytic theta construction.

The new tandem note also constructs the conormal algebra map into dual numbers and keeps the variable-frame connection term. Those results remain compatible inputs; they are not recounted as new results here.

S14.3 2. The original scalar and arithmetic source

Retain the original split scalar

$$G(R) = \{\tau_R\} \sqcup \{r^\bullet : r \in R\}, \quad e_R = 0_R^\bullet.$$

Its original quotient and coefficient maps remain

$$\begin{array}{ccc} G(\mathbb{Z}) & \xrightarrow{G(j)} & G(\mathbb{C}) \\ p_{\mathbb{Z}} \downarrow & & \downarrow p_{\mathbb{C}} \\ \mathbb{Z} & \xrightarrow{j} & \mathbb{C}. \end{array}$$

Here j is the specified unital embedding. The target of $p_{\mathbb{Z}}$ is infinite. Every lifted coefficient map sends e to e and τ to τ before the arithmetic observation.

Keep the source spaces

$$V = \{\phi \in \mathcal{S}(\mathbb{R}) : \phi \text{ even}, \phi(0) = 0, \int_{\mathbb{R}} \phi = 0\},$$

$$\mathcal{B} = \left\{ F \in C^\infty(\mathbb{R}_{>0}) : \sup_{x>0} x^b |D^j F(x)| < \infty \text{ for all } b \in \mathbb{Z}, j \geq 0 \right\}, \quad D = -x\partial_x,$$

$$\Theta\phi(x) = \sum_{n \neq 0} \phi(nx), \quad C_+ = [V \xrightarrow{\Theta} \mathcal{B}], \quad Q = H^1(C_+) = \mathcal{B}/\Theta V.$$

The complex is in degrees 0, 1. Retain

$$\phi_*(x) = (4\pi^2 x^4 - 6\pi x^2) e^{-\pi x^2}, \quad \mathcal{M}\Theta\phi_* = g,$$

$$g(s) = 2\xi(s) = s(s-1)\pi^{-s/2}\Gamma(s/2)\zeta(s).$$

These definitions and the continuous/finite source comparisons are inherited from the supplied cyclic-sum note. Their analytic proofs are not newly re-established in this note.

For a nonempty finite reflection-stable actual zero packet with complete orders, set

$$h(s) = \prod_{\rho \in Z} (s - \rho)^{m_\rho}, \quad E_h = \mathbb{C}[s]/(h), \quad v_h = g/h, \quad v_h = j_h(v_h) \in E_h^\times.$$

For $k \geq 1$, the full tensor arithmetic algebra, generator and unit are

$$B_k = E_h^{\otimes k}, \quad S = s_1 + \cdots + s_k, \quad A_k = M_S, \quad U_k = v_h^{\otimes k}.$$

At a sum λ , its maximal local nilpotent length is

$$\ell_\lambda = \max_{\rho_1 + \cdots + \rho_k = \lambda} \left(1 + \sum_i (m_{\rho_i} - 1) \right).$$

Use the original cyclic algebra and its arithmetic inclusion

$$\chi(S) = \prod_{\lambda} (S - \lambda)^{\ell_\lambda}, \quad C = \mathbb{C}[S]/(\chi), \quad q_k = \deg \chi,$$

$$\alpha : C \hookrightarrow B_k^{S_k}, \quad [P] \mapsto P(A_k)1, \quad \eta = M_{U_k} \alpha : C \hookrightarrow B_k^{S_k}.$$

The first arrow is a unital algebra map. The map M_{U_k} and its inverse $M_{U_k}^{-1}$ are explicit module automorphisms. Thus η retains the arithmetic unit without declaring it to be a unital algebra inclusion.

The source already provides an equivariant retraction $\pi : B_k^{S_k} \rightarrow C$, $\pi\eta = 1$, and retains $\ker \pi$. Together with the full finite jet map and the original signed symmetrization this gives a left inverse to the cyclic inclusion in the top cohomology of $C_+^{\widehat{\otimes} k}$. No cyclic complement is discarded in this continuation.

S14.4 3. The existing canonical metric and its rank-two operator

The actual source map is

$$\mathcal{V}_{h,k}P = P(D_1 + \cdots + D_k)(F_h^{\otimes k}), \quad \mathcal{M}F_h = g/h.$$

It obeys

$$J^{(k)}\mathcal{V}_{h,k} = \eta\pi_\chi, \quad q^{(k)}\mathcal{V}_{h,k} = \sigma_h^{\otimes k}\eta\pi_\chi.$$

The norm remains

$$\|\mathcal{V}_{h,k}P\|^2 = \int_{\mathbb{R}} |P(k/2 + iu)|^2 m_{h,k}(u) du,$$

where

$$a_h(t) = \frac{(g/h)(1/2 + it)}{\sqrt{2\pi}}, \quad w_h = |a_h|^2, \quad \mu_h = \int_{\mathbb{R}} w_h, \quad m_{h,k} = w_h^{*k}.$$

The total mass is μ_h^k . Construct the monic orthogonal polynomials $p_j(S)$ by subtracting lower-degree projections from S^j ; retain their squared norms ω_j , including $\omega_0 = \mu_h^k$.

For $N \geq q_k - 1$, in the fixed remainder coordinates on C , put

$$b_j = [p_j]_\chi, \quad K = \sum_{j=0}^N \frac{b_j b_j^*}{\omega_j}, \quad G = K^{-1},$$

$$Ru = \mathcal{V}_{h,k} \left(\sum_{j=0}^N p_j \frac{b_j^* G u}{\omega_j} \right).$$

These are the actual canonical representative and metric:

$$R^*R = G, \quad J^{(k)}R = \eta, \quad q^{(k)}R = \sigma_h^{\otimes k}\eta.$$

For $A = M_S$ on C , the source's exact boundary control is

$$W = A^*G + GA - kG = G \frac{b_{N+1}b_N^* + b_N b_{N+1}^*}{\omega_N} G.$$

Introduce the metric raising map $G : C \rightarrow C^\#$, $v \mapsto (w \mapsto w^*Gv)$, where $C^\#$ is the space of conjugate-linear functionals. Its inverse is K . Define the corresponding Gram adjoint and control endomorphism by the typed composites

$$A^{\sharp G} = G^{-1} A^* G : C \rightarrow C, \quad H = G^{-1} W = A^{\sharp G} + A - kI_C.$$

Then $H^{\sharp G} = H$ and $\text{rank } H \leq 2$. Reflection pairs λ with $k - \bar{\lambda}$, with equal full length. Hence

$$\text{Tr } H = 2\Re \text{Tr } A - kq_k = 0.$$

Thus the nonzero spectrum of H is $\{+\epsilon, -\epsilon\}$ for the actual nonnegative number

$$\epsilon = \frac{\sqrt{a_N d_N - |c_N|^2}}{\omega_N}, \quad a_N = b_N^* G b_N, \quad d_N = b_{N+1}^* G b_{N+1}, \quad c_N = b_N^* G b_{N+1}.$$

The source reflection gives $\bar{c}_N = -c_N$. Equivalently $\epsilon^2 = \text{Tr}(H^2)/2$. The case $\epsilon = 0$ means $H = 0$ by its G -self-adjointness. No orthonormal replacement of the retained polynomial coordinates is made.

S14.5 4. Exterior control: the allowance does not multiply by exterior degree

Let $1 \leq p \leq q_k$. On $\bigwedge^p C$, define the **additive exterior generator**

$$A^{[p]}(v_1 \wedge \cdots \wedge v_p) = \sum_{j=1}^p v_1 \wedge \cdots \wedge A v_j \wedge \cdots \wedge v_p.$$

Its relation to the multiplicative exterior functor is

$$A^{[p]} = \left. \frac{d}{dt} \right|_{t=0} \bigwedge^p (e^{tA}), \quad \bigwedge^p (e^{tA}) = e^{tA^{[p]}}.$$

In the unscaled increasing-index wedge basis, the Gram matrix is

$$G_{I,J}^{[p]} = \det G_{I,J}.$$

It is positive definite and is the determinant inner product induced from the original G .

Theorem 4.1. The exact exterior control identity is

$$(A^{[p]})^* G^{[p]} + G^{[p]} A^{[p]} - kp G^{[p]} = G^{[p]} H^{[p]}.$$

For $1 \leq p \leq q_k - 1$,

$$-\epsilon G^{[p]} \preceq (A^{[p]})^* G^{[p]} + G^{[p]} A^{[p]} - kp G^{[p]} \preceq \epsilon G^{[p]}.$$

If $\epsilon > 0$, this is the exact optimal allowance. For $p = q_k$ the control form is zero.

Proof. The induced Gram adjoint satisfies

$$(A^{[p]})^{\sharp G^{[p]}} = (A^{\sharp G})^{[p]}.$$

This follows by applying the product rule to the determinant pairing of decomposable vectors. Since $(kI_C)^{[p]} = kpI$, add the two terms to obtain the identity.

For the order bound, keep the G -orthogonal eigenspace decomposition

$$C = L_+ \oplus Z_0 \oplus L_-, \quad H|_{L_+} = \epsilon, \quad H|_{Z_0} = 0, \quad H|_{L_-} = -\epsilon.$$

Both L_+ and L_- have dimension one, and $\dim Z_0 = q_k - 2$. The exterior product of each direct-summand inclusion gives the complete decomposition

$$\begin{aligned} \bigwedge^p C = \bigwedge^p Z_0 \oplus (L_+ \wedge \bigwedge^{p-1} Z_0) \\ \oplus (L_- \wedge \bigwedge^{p-1} Z_0) \oplus (L_+ \wedge L_- \wedge \bigwedge^{p-2} Z_0). \end{aligned}$$

The eigenvalues of $H^{[p]}$ on these four summands are respectively $0, \epsilon, -\epsilon, 0$. The multiplicity of each nonzero eigenvalue is $\binom{q_k-2}{p-1}$; summands with impossible degree are zero modules. This proves every assertion, including the top-degree case. When $\epsilon = 0$, the identity gives the conclusion directly. $\square$

This is the mechanism that makes a determinant-line estimate stronger than testing one eigenvector: a wedge cannot contain the same one-dimensional positive control direction twice.

S14.6 5. The exterior maps live on the original cochain source

Define the unscaled alternating map

$$\text{Alt}_p : \bigwedge^p C \hookrightarrow C^{\otimes p}, \quad v_1 \wedge \cdots \wedge v_p \mapsto \sum_{\pi \in S_p} \text{sgn}(\pi) v_{\pi(1)} \otimes \cdots \otimes v_{\pi(p)}.$$

If $\text{wed} : C^{\otimes p} \rightarrow \bigwedge^p C$ is the exterior quotient, then

$$\text{wed} \text{Alt}_p = p! I.$$

The actual source representative is

$$R_p = R^{\otimes p} \text{Alt}_p : \bigwedge^p C \longrightarrow \mathcal{B}^{\widehat{\otimes} kp}.$$

It retains

$$R_p^* R_p = p! G^{[p]}, \quad J^{(kp)} R_p = \eta^{\otimes p} \text{Alt}_p,$$

$$q^{(kp)} R_p = (\sigma_h^{\otimes k} \eta)^{\otimes p} \text{Alt}_p.$$

The last map is injective: compose with the existing finite-jet/retraction map in each block, then with $\text{wed} / p!$. The factorial is part of this inverse composite; the representative itself is not divided by its norm.

The actual source control is therefore

$$W_p^{\text{source}} = p! \left((A^{[p]})^* G^{[p]} + G^{[p]} A^{[p]} - kp G^{[p]} \right).$$

Both its Gram and its control retain the same literal $p!$. Its relative allowance is the original ϵ .

S14.6.1 5.1 The cochain idempotent and both permutation signs

Let $\mathcal{C}_k = C_+^{\widehat{\otimes} k}$. Let T_π be the actual Koszul permutation on $\mathcal{C}_k^{\widehat{\otimes} p}$. Its top-degree action is $(\text{sgn } \pi)^k P_\pi$, with P_π ordinary block permutation. The chain idempotent for the exterior top-degree component is

$$A_{p,k} = \frac{1}{p!} \sum_{\pi \in S_p} (\text{sgn } \pi)^{k+1} T_\pi.$$

The two top-degree signs multiply to $\text{sgn } \pi$. Its square equals itself by the group-algebra calculation, with the factor $1/p!$ retained. The complementary idempotent $1 - A_{p,k}$ remains, with its own cohomology and trace. The existing projected-homology theorem supplies inclusion and retraction on the original cycle/boundary quotient.

These sign rules are the standard symmetric-monoidal structure on complexes, instantiated here on the retained arithmetic degree k ; they are not an assumption that degree-one vectors commute without sign.

S14.6.2 5.2 Propagate the actual theta primitive

The previous source construction supplies a map

$$K_N^{\text{prim}} : C \rightarrow \mathcal{C}_k^{k-1}, \quad D^{(k)} R - RA = dK_N^{\text{prim}}.$$

Define

$$K_{N,p}^{\text{prim}} = \sum_{j=1}^p (-1)^{k(j-1)} R^{\otimes(j-1)} \otimes K_N^{\text{prim}} \otimes R^{\otimes(p-j)} \text{Alt}_p.$$

The source and target are $\bigwedge^p C$ and $\mathcal{C}_k^{\widehat{\otimes} p, kp-1}$. Applying the tensor differential contributes the same $(-1)^{k(j-1)}$ on the displayed summand. Differentials on the top-degree R factors vanish. Consequently

$$D^{(kp)} R_p - R_p A^{[p]} = dK_{N,p}^{\text{prim}}.$$

This is the exact boundary producing the exterior control form on the original source.

S14.6.3 5.3 Original support and the alternative full-product minimum

Every coefficient map above has its original $G(\mathbb{C})$ -linear reconstructed lift. At a chosen active support label, a term with zero amplitude remains at that label's zero. The sums of differently located primitives use the joins of their actual tensor support masks; the character average uses the corresponding orbit join. External scalar τ maps every input to external absence, while e maps it to its fibre zero. In particular the boundary in the preceding equation is sent by the next internal quotient to the receiving supported zero, not to τ .

There is also an exact comparison with the earlier full-product minimum. Set

$$I_{k,p} = \eta^{\otimes p} \text{Alt}_p, \quad M \geq \max\{pN, kp(\deg h - 1)\}.$$

Let $R_{kp,M}^{\text{full}}$ be the already-constructed canonical full-jet representative. Both it and R_p lie in the stated degree- M source after applying $I_{k,p}$. Hence

$$\Delta = R_p - R_{kp,M}^{\text{full}} I_{k,p}$$

has zero full jets, and its numerator belongs to the original ideal $(h(s_1), \dots, h(s_{kp}))$. Thus it is an original theta boundary with the source's polynomial-division primitive. Orthogonality of the full minimum gives

$$p!G^{[p]} = I_{k,p}^* G_{kp,M}^{\text{full}} I_{k,p} + \Delta^* \Delta.$$

The complete control comparison is

$$\begin{aligned} W_p^{\text{source}} &= I_{k,p}^* W_{kp,M}^{\text{full}} I_{k,p} \\ &\quad + (A^{[p]})^* \Delta^* \Delta + \Delta^* \Delta A^{[p]} - kp \Delta^* \Delta. \end{aligned}$$

This connects the two representative choices without identifying their metrics or discarding their boundary difference.

S14.7 6. A determinant line measures the sum of the positive defects

Let

$$C_{>} = \bigoplus_{\Re \lambda > k/2} C_{\lambda} \subseteq C$$

be the sum of the **full generalized eigenspaces**, of total dimension p . Here $C_{\lambda} \cong \mathbb{C}[S]/(S - \lambda)^{\ell_{\lambda}}$. Write its inclusion as $I_{>} : C_{>} \hookrightarrow C$. Its determinant line has the actual injection

$$\det(C_{>}) = \bigwedge^p C_{>} \xrightarrow{\bigwedge^p I_{>}} \bigwedge^p C \xrightarrow{R_p} \mathcal{B}^{\widehat{\otimes} kp}.$$

The additive exterior generator acts on this line by

$$\zeta_{>} = \text{Tr}(A|_{C_{>}}) = \sum_{\Re \lambda > k/2} \ell_{\lambda} \lambda.$$

Indeed expansion of A on a wedge of a basis keeps only its diagonal coefficients: every off-diagonal replacement repeats one basis vector and has zero wedge. The full nilpotent modules are retained before this determinant map; their dimensions appear in the trace. No simplicity assertion follows: a critical-line Jordan block can have nonzero numerical control while contributing zero real-part defect.

Define

$$L_{h,k} := 2\Re \zeta_{>} - kp = \sum_{\Re \lambda > k/2} \ell_{\lambda} (2\Re \lambda - k).$$

Theorem 6.1. For every admitted N ,

$$0 \leq L_{h,k} \leq \epsilon_{h,k,N}^{\text{cyc}}.$$

Proof. If $p = 0$, the left side is zero. Otherwise reflection implies $p < q_k$. Let v be the nonzero determinant vector of an unscaled basis of $C_{>}$. On this actual eigenline,

$$\frac{v^* W_p^{\text{source}} v}{v^* (p!G^{[p]}) v} = 2\Re \zeta_{>} - kp = L_{h,k}.$$

Theorem 4.1 bounds the same quotient by ϵ . $\square$

The old eigenline argument gave the maximum individual defect. This theorem controls their entire positive sum, with their full lengths. Reflection also gives

$$L_{h,k} = \frac{1}{2} \sum_{\lambda} \ell_{\lambda} |2\Re \lambda - k| = \sum_{\lambda} \ell_{\lambda} |\Re \lambda - k/2|.$$

S14.7.1 6.2 The exact arithmetic volume equation

Let $B_{>} : \mathbb{C}^p \rightarrow C$ be the column map of a fixed unscaled basis of $C_{>}$, and set $G_{>} = B_{>}^* G B_{>}$. Its determinant vector $v_{>}$ has squared source norm

$$\|R_p v_{>}\|^2 = p! \det G_{>}.$$

For the original parameter $a > 0$, let $U_{>}(a) = a^{A|C_{>}}$. Then

$$\det(U_{>}(a)^* G_{>} U_{>}(a)) = a^{kp+L_{h,k}} \det G_{>}.$$

The entire exterior control integrates for $a \geq 1$ to

$$a^{kp-\epsilon} p! \det G_{>} \leq \|R_p \bigwedge^p U_{>}(a) v_{>}\|^2 \leq a^{kp+\epsilon} p! \det G_{>}.$$

Differentiating the norm along $a = e^t$ and applying the exact quadratic inequality proves the bound. Comparing with the exact determinant equality again gives $L_{h,k} \leq \epsilon$. The determinant, its norm, and its weight are all produced by maps from the original arithmetic module.

S14.8 7. Spectral and metric projections are linked explicitly

The determinant argument has an equivalent trace calculation useful for computation. Let $Q_{>} = e_{>}(A)$ be the actual CRT spectral idempotent, where $e_{>}$ is one modulo each positive-defect factor and zero modulo every other factor. It commutes with A .

Choose the original CRT column map $B_{>} : \mathbb{C}^p \rightarrow C$, including every jet. Its G -orthogonal projection is

$$P_{>} = B_{>} (B_{>}^* G B_{>})^{-1} B_{>}^* G.$$

Their exact relationship is

$$Q_{>} P_{>} = P_{>}, \quad P_{>} Q_{>} = Q_{>}, \quad P_{>}^{\sharp G} = P_{>}, \quad (P_{>} - Q_{>})^2 = 0.$$

The first two identities follow from their common range and identity restrictions there. Expanding the square gives the last identity. Invariance of that range gives $P_{>} A P_{>} = A P_{>}$ and

$$\mathrm{Tr}(P_{>} A) = \mathrm{Tr}(Q_{>} A) = \zeta_{>}.$$

Since $\mathrm{Tr}(P_{>} A^{\sharp G})$ is the conjugate of $\mathrm{Tr}(P_{>} A)$,

$$\mathrm{Tr}(P_{>} H) = L_{h,k}.$$

For $\epsilon > 0$, the two G -orthogonal rank-one control projections are the exact polynomials

$$F_+ = \frac{H^2 + \epsilon H}{2\epsilon^2}, \quad F_- = \frac{H^2 - \epsilon H}{2\epsilon^2}.$$

They give the full slack formula

$$L_{h,k} = \epsilon(1 - \eta_{h,k,N}), \quad \eta_{h,k,N} = 1 - \text{Tr}(P_{>}F_+) + \text{Tr}(P_{>}F_-) \geq 0.$$

With $\|T\|_{\text{HS},G}^2 = \text{Tr}(T^\sharp G T)$, this is

$$\eta_{h,k,N} = \|(1 - P_{>})F_+\|_{\text{HS},G}^2 + \|P_{>}F_-\|_{\text{HS},G}^2.$$

Thus the gap has a specified projection meaning rather than an omitted term. This is the elementary rank-two instance of the classical extremal-trace principle.

The retained finite trace has its resolvent description as well:

$$\zeta_{>} = \frac{1}{2\pi i} \int_{\Gamma_{>}} S \text{Tr}((SI - A)^{-1}) dS,$$

where the positively oriented contour encloses exactly the indicated finite blocks. The complementary trace remains

$$\text{Tr } f(A) = \text{Tr}(Q_{>}f(A)) + \text{Tr}((1 - Q_{>})f(A)).$$

Multiplication by $(-1)^k$ gives the inherited cohomological sign. The determinant line occurs in degree kp , retaining $(-1)^{kp}$ for its trace. Split lifts of either projector send an existing class with zero projected amplitude to a supported zero, while the paired projector retains the complementary component.

S14.9 8. Exact sum counting for a nonreal quartet

Take a complete actual nontrivial quartet

$$\rho_{\varepsilon,\eta} = \frac{1}{2} + \varepsilon\delta + i\eta\gamma, \quad \varepsilon, \eta \in \{+1, -1\}, \quad \delta > 0, \quad \gamma > 0,$$

with common full multiplicity m . This is a specification for the following theorem, not an assertion that an off-line zero has been found. The two standard symmetries of $g = 2\xi$ give the full quartet and equal orders from any such actual zero.

The distinct k -fold sums are precisely

$$\lambda_{a,b} = \frac{k}{2} + \delta(2a - k) + i\gamma(2b - k), \quad 0 \leq a, b \leq k.$$

Proof of existence. Let a count positive real signs and b positive imaginary signs. Choose an integer t with

$$\max(0, a + b - k) \leq t \leq \min(a, b).$$

The four occupation counts

$$(t, a - t, b - t, k - a - b + t)$$

are nonnegative and sum to k , with the required two margins. Conversely every tuple has such margins. Since δ and γ are nonzero real numbers, equality of two sums forces equality of both margins. No hypothesis of algebraic independence of zero ordinates is used.

All ordered tuple blocks have the same maximal length

$$\ell_k = 1 + k(m - 1).$$

The nilpotency proof is the original one: the top monomial in $(z_1 + \cdots + z_k)^{k(m-1)}$ has coefficient $(k(m-1))!/((m-1)!)^k \neq 0$. It survives before the next power vanishes. Hence

$$\chi_{h,k}(S) = \prod_{a,b=0}^k (S - \lambda_{a,b})^{\ell_k}, \quad q_k = \ell_k(k+1)^2.$$

For the positive-defect subspace,

$$p = \ell_k(k+1) \left\lceil \frac{k}{2} \right\rceil.$$

Summing its real defects gives

$$\begin{aligned} L_{h,k} &= 2\delta\ell_k(k+1) \sum_{a=\lfloor k/2 \rfloor+1}^k (2a-k) \\ &= 2\delta\ell_k(k+1) \left\lfloor \frac{(k+1)^2}{4} \right\rfloor. \end{aligned}$$

For $k = 2n$, the last sum is $n(n+1)$; for $k = 2n+1$, it is $(n+1)^2$. The imaginary parts cancel in the determinant trace because $\sum_{b=0}^k (2b-k) = 0$.

Combining this calculation with Theorem 6.1 proves

$$2\delta[1 + k(m-1)](k+1) \left\lfloor \frac{(k+1)^2}{4} \right\rfloor \leq \epsilon_{h,k,N}^{\text{cyc}}, \quad N \geq [1 + k(m-1)](k+1)^2 - 1.$$

Every multiplicity is retained. For simple roots the leading term is $\delta k^3/2$; for $m > 1$ it is $\delta(m-1)k^4/2$.

For the two-point reflected pair alone, the analogous exact lower bound is

$$\epsilon_{h,k,N}^{\text{cyc}} \geq 2\delta[1 + k(m-1)] \left\lfloor \frac{(k+1)^2}{4} \right\rfloor.$$

The quartet supplies the additional, rigorously counted factor $k+1$ through its distinct imaginary sums.

S14.10 9. The quantitative target after this construction

The current source formula is still

$$\epsilon_{h,k,N}^{\text{cyc}} = \frac{\sqrt{a_N d_N - |c_N|^2}}{\omega_N}.$$

A contradiction to any actual off-line quartet now follows from a bound

$$\frac{\sqrt{a_N d_N - |c_N|^2}}{k^3 \omega_N} \rightarrow 0$$

along a permitted choice $N = N(k) \geq [1 + k(m-1)](k+1)^2 - 1$, proved for its actual arithmetic measure and complete jet map. For this contradiction the packet h is fixed: constants may depend

on h , and uniformity over all zero locations is not required. The expression itself has not been shown to tend to zero here. The result is a stronger amplification theorem and a weaker sufficient growth target for the next analytic estimate.

For a simple quartet, the source degree is at least quadratic in k . This cost is retained; a fixed-degree central-limit estimate cannot simply be inserted at that growing degree. The previously proved scalar Fisher contraction, with its factor μ_h^{k-1}/k , is not assigned to every polynomial moment.

The existing polynomial derivative formulas supply those actual moments:

$$\begin{aligned}\mathcal{M}_h(z) &= \sum_{j \geq 0} \mu_j \frac{z^j}{j!}, & \mathcal{N}_h(z) &= \sum_{j \geq 0} \nu_j \frac{z^j}{j!}, \\ \int u^j m_{h,k}(u) du &= j! [z^j] \mathcal{M}_h(z)^k, \\ \int u^j \|\partial_u \Psi_{h,k}\|^2 du &= j! [z^j] \left[\frac{1}{k} \mathcal{N}_h \mathcal{M}_h^{k-1} + \frac{k-1}{4k} z^2 \mathcal{M}_h^k \right].\end{aligned}$$

All masses, polynomial degrees and cross terms remain. The new determinant bound uses their already-defined Gram and control matrices rather than changing the source in order to obtain a favourable value.

The real interval $0 < s < 1$ causes no missing quartet case: the alternating zeta series there is positive when grouped into consecutive pairs, while $1 - 2^{1-s} < 0$, so $\zeta(s) < 0$. An actual non-trivial off-line zero is therefore nonreal and is covered by its complete quartet. This argument only identifies the case split; it supplies no upper estimate.

S14.11 10. Deligne architecture and the boundary retained in this step

The inherited Weil-II reading identifies an amplification pattern: carry the same arithmetic spectral information into a cohomological tensor image, obtain a further estimate there, and transport dual control without changing the representation. The finite-field geometric theorem is not being applied on a renamed base.

Here the new characteristic-zero operation is

$$\begin{aligned}& \text{original theta complex over } \mathfrak{b}_\tau \\ & \downarrow \text{existing } k\text{-fold cyclic sum image} \\ & (C, A, R_N, G_N, W_N) \\ & \downarrow \text{signed exterior cochain map} \\ & \left(\bigwedge^p C, A^{[p]}, R_p, p!G^{[p]} \right) \\ & \uparrow \det(C_{>}) \\ & \text{exact sum of positive arithmetic defects.}\end{aligned}$$

The exterior operation controls that determinant line with the **same** allowance as the cyclic image. The original e -relation primitives are carried by $K_{N,p}^{\text{prim}}$; the scalar τ remains external absence. The spectral and metric projectors, their difference, the cyclic complement, the exterior complement and their finite traces are all explicit.

No direct implication from the cardinality of the infinite quotient to positivity is used. Its role is to remain the structural arithmetic quotient throughout the construction, not to be replaced by a finite-field scalar or by the Boolean support observation.

S14.12 11. Verification and reproducibility

The supplied cyclic-sum archive was safely extracted and all 42 entries of its SHA-256 manifest verified. Its 24-method checker was rerun normally and under Python optimization, with matching success records. The new checker contains 22 exact finite test methods; its normal, optimized and deliberately failing results are recorded in checks/.

The Gaussian calculations in the checker are declared algebraic calibrations. Their literal measure is

$$\frac{7^k}{\sqrt{2\pi k}} e^{-u^2/(2k)} du.$$

They test companion matrices, full repeated-root modules, the canonical inverse-moment Gram, exterior factorials, the additive generator, the trace bound and the quartet counting. The mass is 7^k , not one. These examples do not claim that the calibration roots are zeta zeros.

The written arguments are general. Finite tests are regression evidence, not a Lean certificate, interval arithmetic for the actual spectral integrals, or independent certification of the whole analytic source corpus. No repository or other-session branch is changed by this continuation.

S15 Source and relation volume dynamics for the original arithmetic control

Source attribution. Complete source note from the original Toda Volume Control archive. The source and relation Hankel determinants, tilt derivatives, imaginary cross term, first-degree endpoint, both loss squares and original theta input are retained. Its endpoint proof uses a vector symbol for a scalar norm; the explicit typed correction is proved in the integrated Toda bridge, while these original source bytes remain unchanged. The delivered floating evaluations are historical computations without interval or tail certification. The new local theta-tail proof and its separately scoped interval certificate supply that additional evidence for the analytic seed. Neither source asserts the growing-degree arithmetic estimate, and no local Lean execution is attributed to this edition.

S15.1 Results and scope

The preceding exterior construction proves an aggregate lower bound on the canonical arithmetic control. This continuation constructs a scalar route to its upper estimate without selecting another metric on the arithmetic quotient.

The actual canonical quotient determinant is

$$V_N(\theta) = \det G_N(\theta) = \frac{\mathfrak{D}_{N+1}(\theta)}{\mathfrak{B}_{N-q+1}(\theta)}. \quad (1)$$

The numerator is the Gram determinant of the original polynomial source. The denominator is the Gram determinant of the original theta relations in that source. Both determinants come from one retained arithmetic Laplace transform and an explicitly given differential filter. Both obey the classical Hankel-Toda identity. No new general integrable-system theorem is claimed.

For $N \geq q$, put

$$v_N = \log \frac{V_{N-1}}{V_N}, \quad a_{N+1} = \frac{\omega_{N+1}}{\omega_N}, \quad \ell_N = \log V_N, \quad \sigma = \frac{\text{Tr } A - (k/2)q}{i} \in \mathbb{R}.$$

The following is an exact formula, at every real tilt in the stated domain:

$$\boxed{\epsilon_N^2 = a_{N+1}(1 - e^{-v_N})(e^{v_{N+1}} - 1) - (\sigma - \partial_\theta \ell_N)^2.} \quad (2)$$

At $\theta = 0$, ϵ_N is the original allowance in the exterior-amplification note. The new formula retains the cross-term phase through a derivative of a scalar determinant. It is not an estimate that forgets that term.

In particular, with the actual two-step volume ratio

$$\mathcal{R}_N = \frac{V_{N-1}}{V_{N+1}},$$

one obtains the proved finite upper bound

$$\epsilon_N \leq \sqrt{a_{N+1}} \frac{\mathcal{R}_N - 1}{2\sqrt{\mathcal{R}_N}}. \quad (3)$$

Both nonnegative losses in this upper estimate are computed below. The previous aggregate spectral lower bound therefore forces an explicit minimum two-step contraction of the source/boundary volume ratio. This turns the remaining asymptotic question into a comparison between two specified scalar determinant flows. It does not prove that this comparison has the required subcubic bound.

S15.2 1. Integration of the new formalization report

The supplied report identifies verified source commit 2abc351424ba87aeda948a5cfb846e15ed9373d1 in draft PR #21. The current PR metadata and its complete mathematical note were read. The report's successful execution is used with its stated scope; this session did not run Lean or replay the workflow log.

The checked coefficient interfaces are the original quotient derivative

$$\delta_r : A_0/I^{r+1} \longrightarrow A_0/I^r,$$

its square with quotient transitions, the cyclic injection obtained from the **literal** pullback

$$\mathcal{K}_r = \{P : P(S) \in I^r\},$$

and the full multiplier identity

$$\delta_r([uP(S)]) = [uP'(S)] + [(\partial u)P(S)].$$

The report separately identifies the local quotient-basis and CRT interpretation as written proofs. That separation is maintained. Its relation-depth maximum includes attainment and permits the tuple maximizing a collided sum to change with depth.

Here the scalar relation determinant uses the first cyclic relation $\chi = \chi_{h,k,1}$. The weight $|\chi|^2$ is the **squared Hilbert norm of the multiplication map** M_χ ; it is not a declaration that the next contracted ideal is (χ^2) . The map used is displayed in (11). At higher original depth the relevant polynomial remains $\chi_{h,k,r}$, through the checked pullback $\mathcal{K}_r$, not an assumed power of χ .

The empty-packet correction is also kept. For $h = 1$, I is the whole coefficient ring and every positive-depth quotient is zero. The analytic seed g and its mass remain. The split lift $G(0)$ retains two elements. In that case the determinant quotient below is the determinant of the zero-dimensional module, namely 1, and no positive-dimensional inverse or spectral estimate is inferred.

S15.3 2. Original base, coefficient square, and arithmetic source

Keep

$$G(R) = \{\tau_R\} \sqcup \{r^\bullet : r \in R\}, \quad e_R = 0_R^\bullet,$$

and the original square

$$\begin{array}{ccc} G(\mathbb{Z}) & \xrightarrow{G(j)} & G(\mathbb{C}) \\ p\mathbb{Z} \downarrow & & \downarrow p\mathbb{C} \\ \mathbb{Z} & \xrightarrow{j} & \mathbb{C}. \end{array} \quad (4)$$

The target of $p\mathbb{Z}$ remains infinite. The base remains $\mathfrak{b}_\tau$. Every lifted coefficient map fixes external absence and carries represented zero to represented zero.

The analytic source remains

$$V = \{\phi \in \mathcal{S}(\mathbb{R}) : \phi \text{ even}, \phi(0) = \int \phi = 0\},$$

$$\mathcal{B} = \{F \in C^\infty(\mathbb{R}_{>0}) : \sup_{x>0} x^b |D^j F(x)| < \infty \quad \forall b \in \mathbb{Z}, j \geq 0\}, \quad D = -x\partial_x,$$

$$\Theta\phi(x) = \sum_{n \neq 0} \phi(nx), \quad C_+ = [V \xrightarrow{\Theta} \mathcal{B}], \quad Q = \mathcal{B}/\Theta V,$$

$$g(s) = 2\xi(s) = s(s-1)\pi^{-s/2}\Gamma(s/2)\zeta(s).$$

Let h be a nonempty reflection-stable packet of actual zeros with complete orders. Set

$$E_h = \mathbb{C}[s]/h, \quad v_h = g/h, \quad v_h = j_h(v_h) \in E_h^\times, \quad \mathcal{M}F_h = v_h.$$

Fix tensor degree $k \geq 1$. Use the cyclic algebra already constructed:

$$C = \mathbb{C}[S]/\chi, \quad q = \deg \chi \geq 1, \quad c = k/2, \quad A = M_S,$$

$$\eta : C \hookrightarrow (E_h^{\otimes k})^{S_k}, \quad \eta[P] = v_h^{\otimes k} P \left(\sum_i M_{s_i} \right) 1.$$

The source map is

$$\mathcal{V}P = P(D_1 + \cdots + D_k)(F_h^{\otimes k}).$$

It retains

$$J^{(k)}\mathcal{V} = \eta\pi_\chi, \quad q^{(k)}\mathcal{V} = \sigma_h^{\otimes k}\eta\pi_\chi. \quad (5)$$

Here $q^{(k)}$ denotes the original top cohomology quotient; $q = \deg \chi$ denotes a dimension. The full arithmetic unit is still in η .

The scalar norm is

$$\|\mathcal{V}P\|^2 = \int_{\mathbb{R}} |P(c+iu)|^2 m_k(u) du, \quad m_k = w_h^{*k}, \quad w_h(t) = \left| \frac{v_h(1/2+it)}{\sqrt{2\pi}} \right|^2. \quad (6)$$

Its mass is μ_h^k , with $\mu_h = \int w_h$. No measure is divided by that mass.

S15.4 3. One arithmetic function generates both determinant flows

S15.4.1 3.1 Analytic domain

Define

$$M_h(\theta) = \int_{\mathbb{R}} e^{\theta t} w_h(t) dt, \quad Z_{h,k}(\theta) = M_h(\theta)^k. \quad (7)$$

These are analytic on $|\Re \theta| < \pi/2$. Here and below positivity statements concern real θ in that interval.

A direct bound suffices. At $\Re s = 1/2$, bounded partial sums of the alternating series and summation by parts give $|\eta(s)| \leq C(1 + |s|)$. The denominator $|1 - 2^{1-s}|$ is bounded below by $\sqrt{2} - 1$. Stirling's vertical-strip estimate then gives, beyond a fixed compact set,

$$w_h(t) \leq C_h(1 + |t|)^{11/2 - 2 \deg h} e^{-\pi|t|/2}.$$

On the compact set, g/h is entire because the selected zero orders are complete. Thus every differentiated integral is locally uniformly dominated on the displayed strip. This is a sufficient domain, not a claim that it is the maximal analytic continuation of M_h .

Fubini and the exact sum coordinate give

$$Z_{h,k}(\theta) = \int e^{\theta u} m_k(u) du, \quad Z_{h,k}^{(j)}(\theta) = \int u^j e^{\theta u} m_k(u) du. \quad (8)$$

In particular $Z_{h,k}(0) = \mu_h^k$.

S15.4.2 3.2 The source and the relation filter

Let $\bar{\chi}$ mean coefficientwise conjugation, and define the differential operator and its output

$$\mathcal{F}_\chi = \bar{\chi}(c - i\partial_\theta)\chi(c + i\partial_\theta), \quad Z_\chi(\theta) = \mathcal{F}_\chi Z_{h,k}(\theta). \quad (9)$$

Differentiation under the integral proves

$$\boxed{Z_\chi(\theta) = \int |\chi(c + iu)|^2 e^{\theta u} m_k(u) du > 0.} \quad (10)$$

Both factors, their signs, and the coefficient $c = k/2$ remain. This filter is multiplication by a source polynomial under the Laplace transform. It is not the quotient-level derivation δ_r .

For $\mathcal{P}_n = \mathbb{C}[S]_{\leq n}$ and $N \geq q - 1$, the actual source sequence is

$$0 \longrightarrow \mathcal{P}_{N-q} \xrightarrow{M_\chi} \mathcal{P}_N \xrightarrow{\pi_\chi} C \longrightarrow 0, \quad M_\chi P = \chi P, \quad (11)$$

with $\mathcal{P}_{-1} = 0$. Applying $\mathcal{V}$ identifies its first image with the original admitted theta boundaries.

The Laplace observation gives the typed identity

$$\mathcal{L}_\theta(SP) = (c + i\partial_\theta)\mathcal{L}_\theta(P), \quad \mathcal{L}_\theta(P) = \int P(c + iu) e^{\theta u} m_k(u) du.$$

Equation (10) is the Gram observation of M_χ . A source relation has nonzero positive norm before the quotient sends it to a fibre zero.

S15.4.3 3.3 The two determinants

Put

$$\mathfrak{D}_n(\theta) = \det[Z_{h,k}^{(i+j)}(\theta)]_{i,j=0}^{n-1}, \quad \mathfrak{B}_n(\theta) = \det[Z_\chi^{(i+j)}(\theta)]_{i,j=0}^{n-1}, \quad (12)$$

with the actual empty determinants $\mathfrak{D}_0 = \mathfrak{B}_0 = 1$. Every positive-order determinant is positive. A zero norm polynomial would vanish on a full-measure subset of the real line.

The use of u -moments is linked to the original S -basis by

$$S^j = (c + iu)^j = \sum_{r=0}^j \binom{j}{r} c^{j-r} i^r u^r.$$

This triangular coordinate map has determinant $i^{n(n-1)/2}$ on dimension n . Its Gram determinant multiplier is exactly 1, because that determinant has modulus one. No polynomial coefficient or factorial has been dropped.

The determinant has the exact integral representation

$$\mathfrak{D}_n(\theta) = \frac{1}{n!} \int_{\mathbb{R}^n} \prod_{i < j} (u_i - u_j)^2 \prod_{j=1}^n e^{\theta u_j} m_k(u_j) d^n u. \quad (13)$$

For $\mathfrak{B}_n$, insert $\prod_j |\chi(c + iu_j)|^2$. Expanding both Vandermonde determinants and integrating proves the formula, including $1/n!$. The total mass in the first expression scales as $(\mu_h^k)^n$, not as one.

S15.5 4. The quotient determinant is the source/boundary volume ratio

At real θ equip the same polynomial source with

$$\langle P, Q \rangle_\theta = \int \overline{P(c + iu)} Q(c + iu) e^{\theta u} m_k(u) du. \quad (14)$$

Let $H_\theta = L^2(\mathbb{R}, e^{\theta u} m_k(u) du)$. The map $f \mapsto e^{\theta u/2} f$ is an isometry $H_\theta \rightarrow H_0$ with inverse $f \mapsto e^{-\theta u/2} f$. The source in each space is exactly the image of $\mathcal{P}_N$ under evaluation. This is an observation of the original source, not an enlargement of its admitted polynomials.

Let J_N be its quotient matrix and $M_N(\theta)$ its source Gram. Define

$$K_N = J_N M_N^{-1} J_N^*, \quad G_N = K_N^{-1}, \quad \hat{R}_N = M_N^{-1} J_N^* G_N, \quad R_N = \mathcal{V} \hat{R}_N. \quad (15)$$

The adjoints in this calculation use (14). At $\theta = 0$ these are the preceding canonical arithmetic representatives and their original norm. At every θ ,

$$J^{(k)} R_N = \eta, \quad q^{(k)} R_N = \sigma_h^{\otimes k} \eta.$$

Use the source basis

$$1, S, \dots, S^{q-1}, \quad \chi, \chi S, \dots, \chi S^{N-q}.$$

Its change from $1, S, \dots, S^N$ is triangular with diagonal one because the original χ is monic. The Schur complement of its boundary Gram is G_N . This proves

$$V_N := \det G_N = \frac{\mathfrak{D}_{N+1}}{\mathfrak{B}_{N-q+1}}. \quad (16)$$

Equivalently, the determinant line of (11) is mapped by the wedge of the **specified** kernel columns and quotient lifts. Orthogonal quotient representatives supply the Schur complement. This is the exact determinant-line map behind the ratio.

The original support lift is

$$(\lambda_N, P) \mapsto (\lambda_N, [P]_\chi), \quad (\lambda_N, \chi Q) \mapsto (\lambda_N, 0), \quad \tau \mapsto \tau. \quad (17)$$

The determinant $\mathfrak{B}_{N-q+1}$ retains the norm-volume of those nonzero source relations. Replacing that source by its quotient value would incorrectly replace the positive denominator by information-free zeros. The construction evaluates its Gram before applying (17).

For $h = 1$, $\chi = 1$ and $C = 0$. Then $Z_\chi = Z_{h,k}$ and (16) is 1 identically. This is the empty determinant, not an inverse on a nonzero spectral module.

S15.6 5. The two classical Toda identities have their actual arithmetic input

The source determinants satisfy

$$\mathfrak{D}_n \mathfrak{D}_n'' - (\mathfrak{D}_n')^2 = \mathfrak{D}_{n+1} \mathfrak{D}_{n-1}, \quad n \geq 1. \quad (18)$$

The relation determinants satisfy the same equation with $\mathfrak{D}$ replaced by $\mathfrak{B}$.

Here is a proof with the constants retained. For a real positive weight $e^{\theta u} d\mu(u)$, let Q_j be the monic orthogonal polynomial obtained by subtracting lower-degree projections, with norm h_j . Multiplication has the recurrence

$$uQ_j = Q_{j+1} + b_j Q_j + a_j Q_{j-1}, \quad a_j = h_j/h_{j-1}, \quad a_0 = 0,$$

The variable remains u . Differentiating orthogonality gives

$$\partial_\theta Q_j = -a_j Q_{j-1}, \quad \partial_\theta \log h_j = b_j, \quad b_j' = a_{j+1} - a_j.$$

For the last identity, differentiate $h_j b_j = \int u Q_j^2 e^{\theta u} d\mu$, substitute the derivative of Q_j , and use the recurrence. Since $\mathfrak{D}_n = \prod_{j < n} h_j$, the sum telescopes:

$$\partial_\theta^2 \log \mathfrak{D}_n = a_n = \frac{\mathfrak{D}_{n+1} \mathfrak{D}_{n-1}}{\mathfrak{D}_n^2}.$$

This proves (18). The relation weight is the same positive weight multiplied by $|\chi(c+iu)|^2$, which is independent of θ , so the proof applies without alteration to its determinants.

The original S -monic polynomial norms are exactly

$$\omega_j = \frac{\mathfrak{D}_{j+1}}{\mathfrak{D}_j}, \quad \nu_j = \frac{\mathfrak{B}_{j+1}}{\mathfrak{B}_j}. \quad (19)$$

The phases linking monic polynomials in S and u are i^j and i^{-j} ; their norms agree because the phase has modulus one.

For $m = N - q + 1 \geq 0$ this gives the exact quotient-volume curvature

$$\partial_\theta^2 \log V_N = \frac{\mathfrak{D}_{N+2} \mathfrak{D}_N}{\mathfrak{D}_{N+1}^2} - \frac{\mathfrak{B}_{m+1} \mathfrak{B}_{m-1}}{\mathfrak{B}_m^2}. \quad (20)$$

The second term is defined to be zero for $m = 0$, because $\log \mathfrak{B}_0 = 0$. It is not a quotient involving $\mathfrak{B}_{-1}$.

S15.6.1 5.1 The curvature comes from two actual source maps

Let X be multiplication by u on the polynomial realization in H_θ . Let P_N project to $\mathcal{P}_N$ and $P_{\mathcal{D}_N}$ project to the original boundary subspace $\mathcal{D}_N = \chi \mathcal{P}_{N-q}$. Write R for its least-norm polynomial lift.

Differentiating the quotient condition and its orthogonality proves

$$\partial_\theta R = -P_{\mathcal{D}_N} X R. \quad (21)$$

Thus its derivative is an original boundary, with a primitive obtained by literal monic division by χ and the existing theta division maps. Its quotient class and arithmetic jets stay fixed.

Define

$$O_N = (1 - P_N) X R : C \rightarrow \mathcal{P}_{N+1} \cap \mathcal{P}_N^\perp, \quad I_N = P_{\mathcal{D}_N} X R : C \rightarrow \mathcal{D}_N.$$

Direct differentiation, with the derivative of the measure included, yields

$$\boxed{G_N'' - G_N' G_N^{-1} G_N' = O_N^* O_N - I_N^* I_N.} \quad (22)$$

Indeed $G_N' = R^* X R$, $G_N'' = R^* X^2 R - 2R^* X P_{\mathcal{D}_N} X R$, and $R G_N^{-1} R^*$ is the projection to the orthogonal quotient representatives. Their orthogonal direct sum with $\mathcal{D}_N$ is $\mathcal{P}_N$, which proves (22).

Both maps have rank at most one. For O_N this follows from the highest polynomial degree. For I_N^* , multiplication sends every boundary of degree below its highest degree back into $\mathcal{D}_N$, orthogonal to R ; only the highest boundary direction can contribute.

Taking $\text{Tr}(G_N^{-1} \cdot)$ gives (20). The positive source contribution and the negative boundary contribution are retained. Positivity of each Gram separately is not assigned to their difference.

S15.7 6. The phase in the rank-two control is a scalar volume derivative

Put $T = (A - cI)/i$ on C , with $c = k/2$. This is the coefficient operator corresponding to multiplication by u under the explicit ring map $S \mapsto c + iu$. The actual scaling generator is still $A = cI + iT$.

Reflection makes the polynomial $i^{-q} \chi(c + iu)$ real. This assertion follows by substituting $S = c + iu$ into $\chi^\dagger = (-1)^q \chi$. The retained leading phase of $\chi(c + iu)$ is i^q . Its remainder ideal and coefficient extraction are transported through that scalar unit, rather than altering χ in the arithmetic source.

In those real coefficient coordinates let $Q_j(u)$ be the monic source polynomials and $d_j = [Q_j]$. Their norm is ω_j . The metric and representatives have the same quotient definition. Define

$$\ell_N = \log V_N, \quad \sigma = \text{Tr } T \in \mathbb{R}.$$

The exact identity is

$$\boxed{\frac{d_N^* G_N d_{N+1}}{\omega_N} = \sigma - \ell_N'.} \quad (23)$$

To prove it, let $\mathfrak{b}_N = Q_{N+1} - R_N d_{N+1}$ in the polynomial source. It is the actual next boundary and

$$R_N^* \mathfrak{b}_N = -G_N d_{N+1}.$$

Multiplying the least-norm polynomial representative by u , its highest coefficient is $d_N^* G_N / \omega_N$. Therefore, modulo old boundaries,

$$X R_N - R_N T = \mathfrak{b}_N \frac{d_N^* G_N}{\omega_N}.$$

Multiplication by R_N^* eliminates precisely those old boundary terms. Consequently

$$\mathrm{Tr}(G_N^{-1} R_N^* X R_N) = \mathrm{Tr} T - \frac{d_N^* G_N d_{N+1}}{\omega_N}.$$

The left side is ℓ'_N by (21) and differentiation of the norm. This proves (23).

In the original S -polynomial coordinates, $p_j(S)$ maps to $i^j Q_j(u)$. Hence the preceding source cross term satisfies

$$\boxed{\frac{b_N^* G_N b_{N+1}}{\omega_N} = i(\sigma - \ell'_N).} \quad (24)$$

Both the sign and the factor i are retained. In particular an auxiliary real tilt generally creates a nonzero imaginary cross term even from an initially even measure.

S15.8 7. The exact scalar formula and a two-step upper bound

For $N \geq q$, define

$$\delta_N = \frac{V_N}{V_{N-1}}, \quad v_N = -\log \delta_N \geq 0, \quad a_{N+1} = \frac{\omega_{N+1}}{\omega_N}.$$

The nonnegativity follows from the same minimum-norm comparison at nested source degrees. The rank-one kernel update and the matrix determinant lemma give

$$\frac{b_N^* G_N b_N}{\omega_N} = 1 - \delta_N, \quad \frac{b_{N+1}^* G_N b_{N+1}}{\omega_{N+1}} = \delta_{N+1}^{-1} - 1. \quad (25)$$

Substitute (24)–(25) into the inherited exact rank-two radius. This proves

$$\boxed{\epsilon_N^2 = a_{N+1}(1 - e^{-v_N})(e^{v_{N+1}} - 1) - (\sigma - \ell'_N)^2.} \quad (26)$$

All scalar inputs come from (7), (9), and (12). In particular

$$\delta_N = \frac{\omega_N}{\nu_{N-q}}, \quad \delta_{N+1} = \frac{\omega_{N+1}}{\nu_{N-q+1}}.$$

This does not assert that Hankel determinant evaluation is well-conditioned; the exact formula still requires error enclosures for numerical certification.

S15.8.1 7.1 The first admitted degree

At $N = q - 1$, K_{N-1} is not invertible. The displayed formula is replaced by its direct endpoint calculation:

$$\boxed{\epsilon_{q-1}^2 = \frac{\nu_0 - \omega_q}{\omega_{q-1}} - (\sigma - \ell'_{q-1})^2.} \quad (27)$$

Here $\nu_0 = Z_\chi$ is the actual norm of the first source relation. To prove (27), the first q remainder vectors are a basis, so the final included column has leverage one; the next determinant update gives $d_N = \nu_0 - \omega_q$. Formula (24) supplies the phase. No V_{q-2}^{-1} is introduced.

S15.8.2 7.2 Both losses in the finite upper bound

For $N \geq q$, put

$$s_N = \frac{v_N + v_{N+1}}{2}, \quad t_N = \frac{v_{N+1} - v_N}{2}.$$

Direct scalar multiplication gives

$$(1 - e^{-v_N})(e^{v_{N+1}} - 1) = \sinh^2 s_N - (e^{t_N} - \cosh s_N)^2.$$

Thus

$$\boxed{\epsilon_N^2 = a_{N+1} \sinh^2 s_N - a_{N+1} (e^{t_N} - \cosh s_N)^2 - (\sigma - \ell'_N)^2.} \quad (28)$$

In particular, with $\mathcal{R}_N = e^{2s_N} = V_{N-1}/V_{N+1} \geq 1$,

$$\boxed{\epsilon_N^2 \leq a_{N+1} \frac{(\mathcal{R}_N - 1)^2}{4\mathcal{R}_N}.} \quad (29)$$

This upper estimate retains two computable losses: imbalance between consecutive volume contractions and the original cross-term phase. When the bound is too coarse, (26) or (28) is the exact replacement within the same construction.

S15.9 8. What the exterior lower bound forces on these arithmetic volumes

The preceding exterior theorem gives

$$L_{h,k} := \sum_{\Re \lambda > k/2} \ell_\lambda(2\Re \lambda - k) \leq \epsilon_{h,k,N}.$$

It uses the original representative on its determinant line, not a newly chosen scalar metric. Combining it with (29), at $\theta = 0$, proves

$$\boxed{\log \frac{V_{N-1}}{V_{N+1}} \geq 2 \operatorname{arsinh} \left(\frac{L_{h,k}}{\sqrt{a_{N+1}}} \right), \quad N \geq q.} \quad (30)$$

The equivalent inequality without logarithms is

$$4\mathcal{R}_N L_{h,k}^2 \leq a_{N+1} (\mathcal{R}_N - 1)^2.$$

For disjoint successive two-degree steps the logarithms telescope. For every $N_0 \geq q$ and integer $r \geq 1$,

$$\boxed{\log \frac{V_{N_0-1}}{V_{N_0+2r-1}} \geq 2 \sum_{j=0}^{r-1} \operatorname{arsinh} \left(\frac{L_{h,k}}{\sqrt{a_{N_0+2j+1}}} \right).} \quad (31)$$

This is a source-volume consequence for the actual nested relation quotients, not a claim that arithmetic classes disappear when their representative norms decrease. At every degree their jets and original classes remain fixed by (5) and (15).

For a full off-line quartet with displacement $\delta > 0$, height $\gamma > 0$, and common multiplicity m , the previous count is

$$q = [1 + k(m - 1)](k + 1)^2,$$

$$L_{h,k} = 2\delta[1 + k(m - 1)](k + 1) \left\lfloor \frac{(k + 1)^2}{4} \right\rfloor. \quad (32)$$

The quotient (16) and its derivative therefore give an entirely scalar test of the exterior obstruction. For this full quartet m_k and $|\chi(c + iu)|^2$ are even, so $\sigma = 0$ and $\ell'_N(0) = 0$. The phase term vanishes at zero tilt by this **additional** symmetry; it has not been removed from the general formula.

The sufficient subcubic target can now be tested from the quantities

$$\frac{\sqrt{a_{N(k)+1}}}{k^3} \frac{\mathcal{R}_{N(k)} - 1}{2\sqrt{\mathcal{R}_{N(k)}}}, \quad N(k) \geq q, \quad (33)$$

or, more sharply, from the full expression (26). An upper limit of zero for (33) would contradict (32) for that fixed quartet. This continuation proves the formula, the finite upper inequality, and the forced volume lower inequalities. It does not prove that limit.

S15.10 9. The Laplace input can be evaluated from the original theta source

The inverse Mellin representation makes F_h holomorphic in $|\arg z| < \pi/4$. Uniform vertical-strip bounds for v_h permit differentiation and shifts on closed subsectors, and shifting the Mellin contour gives the required rapid endpoint bounds there.

The exact analytic-continuation map is

$$E_\theta F_h(y) = e^{(y+i\theta/2)/2} F_h(e^{y+i\theta/2}).$$

For $|\theta| < \pi/2$, its Fourier transform, with kernel e^{ity} , is

$$\mathcal{F}_+ E_\theta F_h(t) = e^{\theta t/2} v_h(1/2 + it).$$

Contour shift proves the equality; Plancherel yields

$$M_h(\theta) = \int_0^\infty |F_h(e^{i\theta/2}x)|^2 dx. \quad (34)$$

The phase $e^{i\theta/4}$ in E_θ has modulus one and is retained before taking the norm.

Dagger stability gives the analytic identity

$$F_h(1/\bar{z}) = (-1)^{\deg h} \bar{z} \overline{F_h(z)}.$$

Substitute $z = e^{i\theta/2}x$ and change variables on $(0, 1)$. This proves

$$M_h(\theta) = 2 \int_1^\infty |F_h(e^{i\theta/2}x)|^2 dx. \quad (35)$$

Evenness in θ requires conjugation stability as well; it is not inferred just from this endpoint identity.

For the **analytic seed** $h = 1$, keep

$$f_0(z) = 2 \sum_{n \geq 1} (4\pi^2 n^4 z^4 - 6\pi n^2 z^2) e^{-\pi n^2 z^2}.$$

Let $c_1 = -6, c_2 = 4$ and

$$C_{mn}(\theta) = \pi(m^2 e^{i\theta} + n^2 e^{-i\theta}).$$

Substitution into (35), where $\Re C_{mn} > 0$, gives

$$M_1(\theta) = 4 \sum_{m,n \geq 1} \sum_{r,s=1}^2 c_r c_s (\pi m^2)^r (\pi n^2)^s e^{i\theta(r-s)} \frac{\Gamma(r+s+1/2, C_{mn}(\theta))}{C_{mn}(\theta)^{r+s+1/2}}. \quad (36)$$

The complex power is the analytic branch on the open right half-plane agreeing with the positive real power on its positive axis. The sum converges locally uniformly for $|\theta| < \pi/2$, by the exterior Gaussian estimates. Thus all derivatives used by (12) can be taken there. The factor 4 includes both the original two-sided theta sum and the change from the integral to the incomplete gamma function.

The accompanying numerical script evaluated (36) at 50 and 70 digits, with integer cutoffs 6 and 8. Their printed values agree:

$$M_1(0) \approx 1.279007247846485140479533592267193274492,$$

$$M_1(0.1) \approx 1.345907178458249796968220592357629805161.$$

An independent source integral gives

$$M_1''(0) = \|(D - 1/2)f_0\|^2 \approx 13.05554930257055843539268465812319368243.$$

Here $M_1'(0) = 0$. Consequently the first source Toda coefficient for tensor degree k is exactly

$$a_1^{(k)} = k \frac{M_1''(0)}{M_1(0)} \approx 10.207564753485721688865761252237555175 k. \quad (37)$$

This evaluates initial analytic data of the determinant flow. It is not a finite-packet control estimate: for $h = 1$ the arithmetic cyclic quotient is zero. The numerical results have neither directed-rounding enclosures nor a numerical omitted-tail certificate.

S15.11 10. Exact finite checks, an essential phase example, and current endpoint

The checker independently constructs source Gram matrices, quotient maps, representatives, action matrices, and scalar determinants in rational Gaussian fixtures. It compares the scalar result against $\text{Tr}((G^{-1}W)^2)/2$.

For the declared coefficient fixture with weight $7e^{-u^2/2} du / \sqrt{2\pi}$, relation $u^2 + u + 1$, and degree $N = 3$, it obtains

$$\ell'_N(0) = -52/111, \quad \sigma = -1, \quad \epsilon_N^2 = 1156/333.$$

The phase subtraction is $(59/111)^2$, which is nonzero. Omitting it changes the answer. A tilted even-relation fixture gives the same warning: parity at zero tilt is not imposed at another tilt.

Twenty-four exact test methods passed in normal and optimized Python, with identical successful records. Both deliberate-failure controls failed. Repeated roots, source-coordinate phases, mass factors, the minimal-degree endpoint, both Toda equations, the curvature difference, the complete scalar radius, and the supported-zero relation are included. These are finite regression tests, not Lean certificates or verification of infinite arithmetic integrals.

All 34 members named in the preceding exterior package's manifest verified. Its 22-method checker passed a fresh normal run. A combined command attempting a subsequent optimized rerun timed out; no completed optimized rerun is claimed for that inherited suite. The new suite passed in both modes.

The present advance is an upper-estimate mechanism on the exact original family: its input is the one-factor arithmetic Laplace transform; its relation filter is the original cyclic annihilator; its output is the canonical quotient volume and complete control radius. The source-boundary curvature and the positive volume retained before an e -quotient are explicit maps. No uniform subcubic upper estimate, RH/GRH proof, additional Lean execution, or remote repository modification is claimed.

S15.12 References and source boundary

The original source, support, and cohomological conventions are those in the supplied `Tau_Exterior_Trace_Amplification` package and its predecessor `Tau_Cyclic_Sum_Control`. The new formalization report and pinned PR #21 note supply the checked coefficient interfaces, not the analytic estimates in this note.

The general determinant, norm, and Christoffel–Darboux identities are classical. NIST DLMF §18.2(iv), (v), and (ix) records them, including the caution that raw Hankel determinant formulas are often poorly conditioned numerically: <https://dlmf.nist.gov/18.2>. The proof in §5 derives the needed Toda identity directly for the actual exponential deformation, without an isomonodromic or rational-logarithmic-derivative hypothesis. Gamma vertical-strip estimates used in §3 are recorded in DLMF §5.11: <https://dlmf.nist.gov/5.11>.

The finite exterior trace bound remains the theorem proved in the supplied preceding note; this continuation changes its analytic upper-estimate realization, not its algebraic proof or the scope of the parallel formalization.

S16 Supplied conormal derivative, symmetric restriction and uncompiled tower draft

Source attribution. This appendix reproduces the complete supplied mathematical continuation. Its first-person reports about PR 16, PR 18, combined CI, Mathlib inspection and 161 Wolfram checks are historical source statements, not additional verification performed for this edition. Both Lean blocks are retained; the proposed continuation is explicitly uncompiled. The monic-division coordinates and displayed dimension formulas have positive packet degree and tensor degree at least one; the empty packet is handled separately in the integrated proof. Full arithmetic unit and reflection formulas retain the cited source packet hypotheses.

Exact revision. 18f86ad411d0dfafc003aabddf25bccae2d38dcc4006c4d27e5be8aece9347b8

Formal status. Both Lean blocks are source text; the draft has not been compiled for this edition.

Codex's integration has advanced: PR #16 is merged, and the combined frontier/Codex run has now passed. I checked the current repository state and the completed job: it rebuilt the inherited sources, checked the frontier files, imported both developments into one Lean environment, and completed their selected axiom audits. The “combined run pending” sentence in PR #18's description is therefore out of date.

I continued with the new sum-connection note rather than duplicating that work. **The additional result is a complete calculation of what its conormal derivative detects, what it misses, and how that calculation restricts to the symmetric tensor summand.** It also packages the quotient and derivative together as a genuine algebra homomorphism.

The new results below have complete mathematical proofs and exact finite algebra checks. The Lean continuation at the end is an **uncompiled draft**: the local execution service is timing out, and the currently exposed GitHub actions provide no write operation. No remote files were changed in this turn.

S16.0.1 1. The derivative now has a complete quotient construction

Retain the source's notation, with tensor degree $k \geq 1$:

$$P = \mathbb{C}[s_1, \dots, s_k], \quad h_i = h(s_i), \quad I = (h_1, \dots, h_k),$$

$$E = P/I, \quad E^{[2]} = P/I^2, \quad \partial_S = \frac{1}{k} \sum_{i=1}^k \partial_{s_i}.$$

Here h is the original monic packet polynomial, including all multiplicities. These are precisely the relation ideal and derivative in the new attachment.

For any derivation D of a commutative algebra and any ideal I ,

$$\boxed{D(I^{r+1}) \subseteq I^r \quad (r \geq 0).}$$

Proof. An element of I^{r+1} is a sum of multiples of products of $r+1$ elements of I . The product rule differentiates one factor at a time, leaving at least r factors in I . Differentiating an exterior coefficient leaves all $r+1$ factors. Additivity completes the proof.

Consequently the source's maps exist at every order:

$$\delta_r : P/I^{r+1} \longrightarrow P/I^r, \quad [F] \longmapsto [\partial_S F].$$

They commute with the quotient transitions. In particular,

$$\delta_1 : E^{[2]} \longrightarrow E$$

is a derivation **along** the quotient $\pi : E^{[2]} \rightarrow E$:

$$\boxed{\delta_1(xy) = \pi(x)\delta_1(y) + \pi(y)\delta_1(x).}$$

This is the appropriate product rule; δ_1 is not an endomorphism of the arithmetic algebra E .

Monic division constructs all the retained layers There is a unique finite expansion

$$F = \sum_{\alpha \in \mathbb{N}^k} h_1^{\alpha_1} \cdots h_k^{\alpha_k} r_\alpha, \quad \deg_{s_i} r_\alpha < d := \deg h.$$

Existence follows by repeated monic division in the separate variables. For uniqueness, the leading monomials of

$$h^\alpha s^\beta, \quad 0 \leq \beta_i < d,$$

have exponent vectors $d\alpha + \beta$, which are distinct. A finite dependence therefore has a unique largest leading monomial and cannot cancel.

This gives explicit coordinates—not just an existence statement—for

$$I^r/I^{r+1} \cong E[\eta_1, \dots, \eta_k]_r, \quad \eta_i \longleftrightarrow [h_i].$$

In particular,

$$I/I^2 \cong E^k, \quad (a_i) \longmapsto \left[\sum_i h_i \tilde{a}_i \right],$$

and

$$\dim_{\mathbb{C}} P/I^{r+1} = d^k \binom{k+r}{k}.$$

On the associated graded, the derivative is exactly

$$\boxed{\text{gr}(\partial_S) = \frac{1}{k} \sum_i [h'_i] \partial_{\eta_i}.$$

Indeed, differentiating a coefficient of $h^\alpha r_\alpha$ stays in $I^{|\alpha|}$, while differentiating one h_i -factor lowers the ideal order and contributes the literal exponent α_i . This proves the higher-layer formula in the attachment without deleting those exponent factors.

The standard conormal construction supplies the map

$$I/I^2 \longrightarrow \Omega_{P/\mathbb{C}} \otimes_P E.$$

The calculation here identifies its coordinates for this particular ideal and then contracts it by the specified sum direction; those are distinct operations (The Stacks Project Authors, n.d., Tag 00S0). (The Stacks Project)

S16.0.2 2. The exact information detected by the sum derivative

Let

$$A_h = \mathbb{C}[s]/(h), \quad E = A_h^{\otimes k},$$

and write

$$c_i = [h'(s_i)] \in E.$$

Under the preceding conormal coordinates, the restriction of δ_1 is the E -linear map

$$\partial_N : E^k \longrightarrow E, \quad (a_1, \dots, a_k) \longmapsto \frac{1}{k} \sum_i c_i a_i.$$

The attachment gives this row. The following kernel, cokernel, and rank calculations are additional deductions.

Let

$$b = \deg \gcd(h, h').$$

Over $\mathbb{C}$, if h has q distinct roots, then

$$b = d - q = \sum_{\rho} (m_{\rho} - 1).$$

The image and cokernel are

$$\mathrm{im} \partial_N = (c_1, \dots, c_k) \subseteq E,$$

$$\mathrm{coker} \partial_N \cong (\mathbb{C}[s]/(h, h'))^{\otimes k}.$$

Proof. The image is the ideal generated by the row entries because $1/k$ is invertible. Quotienting E by those entries imposes $h(s_i) = h'(s_i) = 0$ in each separate variable, giving the displayed tensor product.

Therefore

$$\mathrm{rank}_{\mathbb{C}} \partial_N = d^k - b^k, \quad \dim_{\mathbb{C}} \ker \partial_N = (k-1)d^k + b^k.$$

These formulas separate two sources of information lost by this particular observation.

When h is squarefree, $b = 0$, so the contracted derivative is onto. Nevertheless, for $k > 1$ its kernel still has dimension $(k-1)d^k$: **contracting to the sum direction does not observe every relative conormal direction, even without repeated roots.**

When roots are repeated, the additional term b^k records the failure of the Jacobian entries to generate the unit ideal.

For example, take the declared algebraic calibration

$$h(s) = s^2, \quad k = 2, \quad E = \mathbb{C}[x, y]/(x^2, y^2).$$

Then

$$\partial_N(a, b) = xa + yb.$$

Its image is

$$\text{span}\{x, y, xy\},$$

so its rank is three and its kernel has dimension five. The conormal vector $(x, 0)$ is nonzero but lies in that kernel. Its representative is x^3 modulo

$$I^2 = (x^4, x^2y^2, y^4),$$

so the retained relation is genuinely nonzero before observation.

These are ranks of the **conormal restriction**, not of the whole map $\delta_1 : E^{[2]} \rightarrow E$. The latter is onto: in coordinates

$$S = \sum_i s_i, \quad z_i = s_i - S/k,$$

one has $\partial_S = \partial/\partial S$, and a polynomial primitive is obtained by integrating its powers of S . The same argument makes every δ_r onto.

Package the quotient and derivative as one algebra map Introduce an ordinary formal square-zero parameter ϵ , distinct from the supported scalar e . Define

$$\boxed{\mathcal{J}_S^1 : E^{[2]} \longrightarrow E[\epsilon]/(\epsilon^2), \quad x \longmapsto \pi(x) + \epsilon \delta_1(x).}$$

This is a unital $\mathbb{C}$ -algebra homomorphism. Multiplication follows from the relative product rule:

$$(\pi x + \epsilon \delta x)(\pi y + \epsilon \delta y) = \pi(xy) + \epsilon \delta(xy).$$

Thus the source's two differently typed maps can be retained together in a single multiplicative observation. Its kernel is exactly

$$\ker \mathcal{J}_S^1 = \{n \in I/I^2 : \partial_N n = 0\},$$

and consequently

$$\boxed{\dim \ker \mathcal{J}_S^1 = (k-1)d^k + b^k, \quad \dim \text{im } \mathcal{J}_S^1 = 2d^k - b^k.}$$

The proof of the image dimension is the exact sequence

$$0 \longrightarrow \epsilon \text{ im } \partial_N \longrightarrow \text{im } \mathcal{J}_S^1 \longrightarrow E \longrightarrow 0.$$

This also describes the precise quotient of the first thickening seen by the sum derivative. It does not silently identify that quotient with the entire first thickening.

Retaining every first derivative is a different observation If all coordinate derivatives are retained, the map is

$$\mathcal{J}_{\text{all}}^1 : E^{[2]} \longrightarrow E \oplus E^k, \quad [F] \longmapsto ([F], ([\partial_i F])_i),$$

where E^k is a square-zero ideal in the target.

On $I/I^2 \cong E^k$, its derivative component is

$$(a_i) \longmapsto (c_i a_i)_i.$$

Each multiplication map M_{c_i} has kernel dimension $b d^{k-1}$. Hence

$$\dim \ker \mathcal{J}_{\text{all}}^1 = k b d^{k-1}.$$

In the squarefree case this full first-jet map is an algebra isomorphism onto the square-zero extension $E \oplus E^k$. With repeated roots it still loses the explicitly computed Jacobian-annihilator directions, which remain in the higher source layers.

The split lifts retain their original meaning throughout:

$$G(\pi)(n^\bullet) = e_E, \quad G(\mathcal{J}_S^1)(n^\bullet) = (\epsilon \partial_N n)^\bullet.$$

External absence maps to external absence. This is a calculation of a retained relation before quotienting, not a rule that differentiates e into a nonzero scalar. The attachment makes that distinction explicitly.

S16.0.3 3. This calculation restricts to the symmetric tensor construction

The preceding maps commute with simultaneous permutation of variables and conormal indices. Let

$$N = I/I^2 \cong E^k, \quad T = \mathbb{C}[s]/(h, h').$$

The cokernel sequence is equivariant:

$$N \xrightarrow{\partial_N} E \longrightarrow T^{\otimes k} \longrightarrow 0.$$

Taking S_k -invariants remains exact: given an invariant element in an image, average any preimage with the literal factor $1/k!$. Thus

$$\text{coker}(\partial_N : N^{S_k} \rightarrow E^{S_k}) \cong (T^{\otimes k})^{S_k}.$$

The invariant conormal domain has the explicit description

$$N^{S_k} \cong A_h \otimes (A_h^{\otimes(k-1)})^{S_{k-1}}.$$

An invariant tuple is determined by its first component, which is invariant under permutations fixing the first index; the other components are its prescribed translates. This constructs both directions of the identification.

Consequently,

$$\dim N^{S_k} = d \binom{d+k-2}{k-1},$$

$$\text{rank } \partial_N^{S_k} = \binom{d+k-1}{k} - \binom{b+k-1}{k},$$

and

$$\dim \ker \partial_N^{S_k} = d \binom{d+k-2}{k-1} - \binom{d+k-1}{k} + \binom{b+k-1}{k}.$$

For $b = 0$, the final binomial is zero.

For $h = s^2$ and $k = 2$, the symmetric conormal domain has dimension four, the symmetric arithmetic target has dimension three, and the restricted derivative has rank two. Its kernel still has dimension two.

These are ordinary variable-permutation invariants of the relation algebra. To place them in the original cochain construction, use the source's **signed chain idempotent**

$$S_k = \frac{1}{k!} \sum_{\pi \in S_k} \text{sgn}(\pi) T_\pi.$$

Its two top-degree signs produce precisely the ordinary symmetric tensors used here. Replacing it by the unsigned chain average would change the selected summand.

This gives the smaller cohomological calculation its own exact derivative kernel; selecting the symmetric summand does not amount to presuming that the remaining relative information vanishes.

S16.0.4 4. The arithmetic unit and trace remain attached

The new note retains

$$U = \prod_i (g/h)(s_i)$$

and its Taylor class $\widehat{U} \in E^{[2]}$. The relative Leibniz rule proves

$$\delta_1(\widehat{U}x) = U \delta_1(x) + \delta_1(\widehat{U})\pi(x).$$

On a conormal class n , the second term vanishes:

$$\delta_1(\widehat{U}n) = U \partial_N n.$$

Because U is a unit, this arithmetic multiplication changes neither the kernel nor the ranks calculated above. It is nevertheless retained in the actual map, rather than assigned the value one. This is the source's specified unit correction.

There is also an important distinction between the **sum-Jacobian response** and the **product Jacobian used by the full product trace**.

Multiplication by

$$\prod_i h'(s_i)$$

on $E = A_h^{\otimes k}$ has rank

$$\boxed{q^k},$$

where q is the number of distinct roots of h . Its kernel has dimension

$$d^k - q^k$$

and is the nilradical of E .

Proof. At a root ρ of multiplicity m , write

$$h(\rho + z) = z^m u_\rho(z), \quad u_\rho(0) \neq 0.$$

Modulo z^m ,

$$h'(\rho + z) = m u_\rho(0) z^{m-1}.$$

Multiplication by this element has one-dimensional image and kernel (z) . At a k -tuple of roots, the product Jacobian similarly sends the constant coefficient to a nonzero multiple of

$$z_1^{m_1-1} \cdots z_k^{m_k-1}$$

and annihilates the maximal ideal. There is one image dimension per root tuple, giving q^k .

This is not the rank $d^k - b^k$ of the contracted conormal row. The two operators use the same derivative factors but perform different observations.

The one-variable trace identity remains exact. Let

$$\lambda_h([P]) = \sum_{\rho} \operatorname{Res}_{s=\rho} \frac{P(s)}{h(s)} ds.$$

Then

$$\boxed{\lambda_h(h'P) = \operatorname{Tr}(M_P \mid A_h).}$$

Locally, $h'/h = m_\rho/(s - \rho) + u'_\rho/u_\rho$, so its residue against P is $m_\rho P(\rho)$. Multiplication by P on the local algebra has that same trace because its nilpotent terms have zero diagonal.

Writing $v_h = j_h(g/h)$ and $\varepsilon_h = v_h^{-1}$, the actual arithmetic pairing gives

$$\begin{aligned} \mathcal{R}_Z(f, j_h(g')P) &= \lambda_h(\varepsilon_h f^\dagger v_h h'P) \\ &= \lambda_h(f^\dagger h'P) \\ &= \operatorname{Tr}(M_{f^\dagger P} \mid A_h). \end{aligned}$$

Both unit factors are present before cancellation. This is the algebraic form of the attachment's observation of

$$(\log x)\Theta(P(D)\phi_*),$$

with the original $g = 2\xi$, reflection, and multiplicities retained.

S16.0.5 5. Lean continuation against the integrated library

The merged Codex source already supplies

`SplitZero.RelationLayer.derivative`

as the quotient map induced by a linear map that carries the source relations into the target relations. I read its implementation and reused that interface below rather than introducing another quotient.

The following proposed `SplitZeroConormalTower.lean` proves the ideal-power containment from the derivation law, uses it to construct every descended derivative, proves compatibility between levels, and computes the derivative of an original relation. Its proof scripts are complete, but **compilation has not been checked**.

The derivation and ideal-product APIs used here were checked against the repository's existing Mathlib revision, rather than assumed from a different release. That source inspection does not substitute for running Lean.

S16.0.6 Verification and the remaining quantitative connection

The fresh Wolfram calculations passed **161 exact checks**: conormal ranks and invariant restrictions, full first-jet ranks, ideal-square annihilation, residue traces, product-Jacobian ranks, higher derivative identities, and retained-unit trace identities. The fixtures include squarefree polynomials, repeated roots, mixed multiplicities, and tensor degrees through three. An initial variable-binding error in my checker was corrected before the successful runs. These are finite algebra checks, not a new Lean certificate or evaluations of arithmetic zero locations.

The new result does not identify the Hilbert-space normal map N_u with the algebraic conormal module I/I^2 . The attachment's filtered graph supplies the stated route from the full derivative to arithmetic jets. Its exact scalar identity

$$\mathcal{I}_{h,k} + 4 \int \|n_k(u)\|^2 du = \frac{\mu_h^{k-1}}{k} \mathcal{I}_h$$

retains the Hilbert normal contribution; the conormal calculations above now identify the algebraic kernel encountered by the subsequent sum-direction observation. Those two pieces must remain separately typed when estimating the original weight-control form.

The continuation now provides an exact first-jet algebra map, its full retained kernel, the corresponding symmetric restriction, and all-order quotient derivatives. Codex can build those on the merged quotient library without recreating the scalar, homology, or boundary-control implementations.

Formal status. The associated two Lean modules and observed remote CI evidence are archived separately. No local Lean execution is attributed to this edition.

S17.1 Original conormal and cyclic relation towers

S17.1.1 Scope and source reconciliation

This add-only continuation starts from main at a4494fba4968db837a8af6fcb952c8688cd5d1da. It retains the merged Codex quotient/homotopy/boundary implementation, the merged finite-frontier implementation, and the reviewed sum-connection note. It uses the owner's attached **Handoff: sum-generated arithmetic control**, especially targets 1, 2, 4 and 8. The current upload is an analytic/algebraic continuation with a separately reported 24-method finite checker; it is not a Lean certificate. The local execution service failed before its ZIP could be opened, so neither the ZIP manifest nor that checker has been independently rerun here.

Two actual GitHub corrections are incorporated, not merely acknowledged:

- Commit 600ab7a527f7a626c162bf0199d093d454b86c14 makes the nonempty hypothesis explicit in the monic-freeness argument and calculates $h=1$ separately. Every positive-depth relation ideal for $h=1$ is the whole polynomial ring. The corresponding underlying quotients are zero, while the split lift still retains tau and supported zero. The analytic theta seed and its mass do not disappear. `ConormalTower.top_level_zero` checks the full-ideal quotient at every level.
- Commit 7aec03a93b66d3d97fbf6f7042f58bb2c1019543 corrects the completed integration audit to 68 selected declarations and enables the existing frontier workflow on main and relevant pull requests. This branch inherits those files unchanged. The current 68-target audit, not the historical 66-target description, is rerun by the added workflow.

The original scalar G , e , tau, arithmetic projection to the infinite ring, reconstructed carriers, quotient transports and theta normalization $g=2$ xi are unchanged. No claim about a global arithmetic small-control estimate follows from the present algebraic results.

S17.1.2 1. An actual derivative between consecutive original quotients

Let R and A be commutative rings, A an R -algebra, I an ideal of A , and D an R -derivation of A . Then

$D(I^{(r+1)})$ is contained in I^r , $r \geq 0$.

Proof: use induction on r and the additive generation of an ideal product by products. For a in $I^{(r+1)}$, b in I , the Leibniz terms $a D(b)$ and $b D(a)$ both lie in $I^{(r+1)}$: the first by the ideal property, the second by the induction hypothesis. At $r=0$ the target ideal is the whole ring.

SplitZeroConormalTower.lean implements that proof as `deriv_mem_pow`. It then uses the merged `SplitZero.RelationLayer.derivative` to construct

$\text{delta}_r : A/I^{(r+1)} \rightarrow_R A/I^r, [x] \mapsto [D x]$.

It separately constructs the quotient projection p_r between the same types and proves

$p_r \text{delta}_{(r+1)} = \text{delta}_r p_{(r+1)}$.

The derivative is not an endomorphism of A/I . These are coefficient-linear maps on the actual original quotient types, not new quotient carriers. At a retained relation z in I ,

$\text{delta}_1([z a]) = [a D(z)]$.

For the full arithmetic multiplier u , the implemented formula is

$\text{delta}_r([u x]) = [u D(x)] + [x D(u)]$.

It applies in particular to the retained Taylor unit, without assigning the unit the value one or deleting its derivative. The definitions work for arbitrary commutative rings and do not assume characteristic zero or squarefreeness.

S17.1.3 2. The exact cyclic pullback, before a polynomial is used to describe it

Fix S in A . At each depth define the actual coefficient submodule

$K_r = \{P \text{ in } R[X] : P(S) \text{ belongs to } I^r\}$.

The implementation calls this `cyclicLevel`; it is literally the comap of the original relation submodule along `Polynomial.aeval\S`. Its constructed quotient map is

$\alpha_r : R[X]/K_r \rightarrow_R A/I^r, [P] \mapsto [P(S)]$.

`evaluation_injective` proves injectivity by the two original quotient equality criteria. No assumed injectivity of polynomial evaluation is required. This implementation is a linear map; its usual algebra-homomorphism packaging is not claimed as a new bundled declaration.

If $D(S)=1$, Mathlib's formal polynomial chain rule gives

$D(P(S)) = P'(S)$.

Thus P in $K_{(r+1)}$ implies P' in K_r . The code constructs the cyclic derivative and proves the full square

$$\begin{array}{ccc} R[X]/K_{(r+1)} & \xrightarrow{-d/dX-} & R[X]/K_r \\ \downarrow \alpha_{(r+1)} & & \downarrow \alpha_r \\ A/I^{(r+1)} & \xrightarrow{\quad D \quad} & A/I^r. \end{array}$$

The actual unit comparison is also proved:

$\text{delta}_r([u P(S)]) = [u P'(S)] + [D(u) P(S)]$.

The final term need not be in the cyclic image. The equation retains its larger target. Most importantly, K_r is not replaced by K_1^r . The explicit annihilator calculation below explains the difference.

S17.1.4 3. Exact local maximum, including an attaining monomial

Here the base field is $\mathbb{C}$. Let $k \geq 1$, $d \geq 1$, $r \geq 1$ and write the complete packet polynomial as

$$h(s) = \prod_{\rho} (s - \rho)^{m_{\rho}}.$$

For a root tuple $\mathbf{\rho} = (\rho_1, \dots, \rho_k)$, put $m_i = m_{(\rho_i)}$ and $y_i = s_i - \rho_i$. Locally the ideal $(h(s_i))$ is $(y_i^{m_i})$, because each remaining factor is a unit. In the quotient by its r -th power the monomial basis is precisely

$$y^{\mathbf{a}} \text{ such that } \sum_i \lfloor a_i / m_i \rfloor < r.$$

Write $a_i = m_i q_i + t_i$ with $0 \leq t_i < m_i$. Its total degree satisfies

$$\sum_i a_i \leq \sum_i (m_i - 1) + (r - 1) \max_i m_i.$$

The proof uses $\sum_i q_i \leq r - 1$ and bounds each m_i by its maximum. This bound is attained: choose j with $m_j = \max_i m_i$, let every $t_i = m_i - 1$, let $q_j = r - 1$, and let every other $q_i = 0$.

SplitZeroCyclicDepth.lean formalizes the quotient/remainder predicate, the degree bound, that explicit exponent vector, and attainment. The floor-sum formulation is linked through Euclidean division. This is an all-index, all-depth result, not a finite calibration. The additional algebraic identification of these monomials with the polynomial quotient and the characteristic-zero multinomial step below have written proofs, not an additional Lean certificate in these two modules.

Let $N = y_1 + \dots + y_k$. Its exact nilpotency index is

$$L_r(\mathbf{\rho}) = 1 + \sum_i (m_i - 1) + (r - 1) \max_i m_i.$$

Indeed every monomial of total degree L_r is killed. The attaining monomial at degree $L_r - 1$ has coefficient

$$(L_r - 1)! / \prod_i a_i!$$

in $\mathbb{N}^{L_r - 1}$, a nonzero positive integer in characteristic zero. Distinct surviving monomials cannot cancel. This proves both vanishing and minimality.

The proof also counts the local dimension as

$$(\prod_i m_i) * \text{binomial}(k + r - 1, k).$$

The q_i with sum less than r give the binomial factor, and their remainders give the product factor.

S17.1.5 4. Collisions require a maximum at every depth

Set $S = \sum_i s_i$. At a collided sum λ , take the maximum over all root tuples with that sum:

$$\begin{aligned} \text{ell}(\lambda, r) &= \max_{\sum \rho_i = \lambda} L_r(\mathbf{\rho}). \\ \chi_r(X) &= \prod_{\lambda} (X - \lambda)^{(\text{ell}(\lambda, r))}. \end{aligned}$$

The Chinese-remainder decomposition and the exact local nilpotency prove

$$I^{\wedge r} \text{ intersect } \mathbb{C}[S] = (\chi_r(S)).$$

The same annihilator is obtained in the variable-permutation invariant subalgebra because every polynomial in S is already invariant. Thus α_r identifies the cyclic algebra $C[X]/(\chi_r)$ with its actual image, with no squarefree simplification.

The maximizing tuple can change with depth. In the declared calibration packet with roots 0,1,2 of multiplicities 5,4,1, respectively, the sum $\lambda=2$ in tensor degree two has

$$\text{ell}_r(2, r) = \max(5r, 4r+3).$$

At depths 1,...,5 the orders are 7,11,15,20,25. A tuple chosen only at depth one is insufficient for the whole tower. This is an algebraic test packet, not a statement about actual zeta zeros.

For every λ ,

$$\begin{aligned} \text{ell}_r(\lambda, r+1) &\geq \text{ell}_r(\lambda, r)+1, \\ \text{ell}_r(\lambda, r) &\leq r \text{ell}_r(\lambda, 1). \end{aligned}$$

The first follows by retaining a maximizing tuple from depth r ; its next slope is a positive multiplicity. For the second, note $\max_i m_i \leq 1 + \sum_i (m_i - 1)$ for every tuple. Hence

$$\begin{aligned} \chi_r &\text{ divides } \chi_{r+1}, \\ \chi_r &\text{ divides } \chi_{r+1}', \\ \chi_r &\text{ divides } \chi_1^r. \end{aligned}$$

The last divisibility supplies the stated surjection $C[X]/(\chi_1^r) \rightarrow C[X]/(\chi_r)$, not an equality. For $h(s)=(s-\rho)^2$ and $k=2$,

$$\begin{aligned} \chi_r(X) &= (X-2\rho)^{(2r+1)}, \\ \chi_1(X)^r &= (X-2\rho)^{(3r)}. \end{aligned}$$

They differ as soon as $r>1$. The derivative maps $C[X]/\chi_{r+1} \rightarrow C[X]/\chi_r$ are onto over C : integrate any polynomial representative, then take its source class. Their kernel dimensions are $\deg(\chi_{r+1}) - \deg(\chi_r)$.

For the empty packet $h=1$, handled separately as required by the GitHub correction, $I=P$, $K_r=C[X]$, and $\chi_r=1$ for all positive depths. The cyclic arithmetic quotient is zero. No maximum over an empty tuple set or inverse of a zero-dimensional Gram matrix is used to define it. The original nonzero analytic seed remains available as an analytic object.

S17.1.6 5. Explicit equivariant retraction of the cyclic summand (written proof)

This checks the handoff's retraction formula, including its inverse factor. On a λ -primary part M of the symmetric finite algebra, let $N=S-\lambda$, $N^{\text{ell}}=0$, and let w be the λ -component of the retained arithmetic unit U . Exact maximality gives $N^{(\text{ell}-1)}w \neq 0$. Choose the stated top-monomial coefficient functional θ with $\theta(N^{(\text{ell}-1)}w) \neq 0$. If it is realized first on an ordered root component, it can be restricted to the invariant subspace; the component of the symmetric vector is still detected.

Define

$$\pi_0(v) = \sum_{j=0}^{(\text{ell}-1)} \theta(N^{(\text{ell}-1-j)}v) X^j \bmod X^{\text{ell}}.$$

Coefficient comparison gives $\pi_0(Nv)=X \pi_0(v)$: the constant term on the left is $\theta(N^{\text{ell}}v)=0$ and the other coefficients shift exactly. Put $c=\pi_0(w)$. Its constant coefficient is nonzero, so it is invertible modulo X^{ell} . Explicitly, if $c=c_0(1+n)$, the inverse is $c_0^{-1} \sum_{j=0}^{(\text{ell}-1)} (-n)^j$.

Then $\pi=c^{-1}\pi_0$ satisfies

$$\pi(P(N)w) = P(X) \bmod X^{\text{ell}}.$$

Therefore the unit-weighted cyclic injection η has an S -equivariant left inverse. Summing over λ constructs the full retraction, and $\ker(\pi)$ is an invariant complement. This is a module splitting, not an assertion that π is an algebra map or that the summands are orthogonal for the canonical arithmetic Gram. All cross terms under that splitting remain.

This cyclic summand retains each amplified value $k \rho$; collided repeated pure tensors need not equal the particular cyclic eigenvector. The cyclic residue trace and the full symmetric trace have their distinct multiplicities. No part of the present calculation identifies those traces or drops the U -dagger U factor in the ambient arithmetic pairing.

S17.1.7 6. Formal versus analytic scope

The new formal outputs are the ideal-power derivative, actual quotient transitions, exact cyclic pull-back/injection, derivative square, unit rule, full-ideal case, and the all-degree attained monomial ceiling. Existing SplitZero support maps lift their coefficient maps at the original labels. No duplicate scalar construction or alternative homology core is introduced.

The exact χ_r annihilator, local basis/multinomial identification and the retraction in Sections 3-5 are supplied here as complete written arguments. Their finite calibrations are separate Python tests. The new upload's analytic cyclic convolution measure, canonical Gram, differentiated moments, rank-two control and full trace comparison remain its separately stated inputs and targets. This work does not independently certify that archive, an analytic moment enclosure, or a tensor-uniform small-control bound.

S17.1.8 Reproduction

Run the added SplitZero\conormal\cyclic\tower workflow on this branch. It installs unchanged Lean 4.31.0 and Mathlib fabf563a7c95a166b8d7b6efca11c8b4dc9d911f, rebuilds all inherited modules, checks every new source with `- \/-trust=0 \-DwarningAsError=true`, imports the combined sources, and rejects any selected transitive axiom outside `propept`, `Classical.choice` and `Quot.sound`. It reuses the previously tested axiom parser. The original core's byte pin is checked by the inherited prepare script.

The new finite checker directly multiplies the nilpotent sum in explicit local monomial quotients. It tests attainment and its literal multinomial coefficient, collided maxima, derivative divisibility, local dimensions and the $h=1$ branch, in normal and optimized Python with deliberate-failure controls. These finite tests do not replace the general Lean proofs or the written polynomial arguments. The final PR record identifies the exact completed run; no pending run is a certificate.

S18 The coordinating Zeta contribution: determinant losses and spectral coupling

Source attribution. Complete mathematical note supplied by the coordinating Zeta task on 13 September 2026. The direct sum of the two exact identities retains the original quotient metric, phase, spectral coupling and compression remainder. Its full formulas, domains, endpoint scope and Sylvester comparison are reproduced as supplied. The integrated bridge gives the same join with its complete derivation. No asymptotic estimate or novelty claim is inferred.

Exact revision. 71e275a8543448e57bcfafc5ead8cf3c7f98d594ae994582d1180999d98c6370

Source file. sources/web_toda_parent_join/PARENT_EXACT_JOIN.md

This appendix reproduces the complete proof note as a dated source witness. Descriptions of what is new, unavailable, or left for continuation refer to that source revision. The current local continuations and their proofs are in Part I. The appendix is attributed to its originating web contribution; it is not presented as a newly discovered local proof.

Source SHA-256. 71e275a8543448e57bcfafc5ead8cf3c7f98d594ae994582d1180999d98c6370

Formal status. Complete written join of Toda (28) and frozen exterior identity E8; no new Lean execution.

S18.1 Exact join: determinant losses and spectral coupling

This short continuation joins two already written identities on the same finite arithmetic packet and its original least-norm metric. It does not replace that metric or claim an asymptotic estimate. It is a direct algebraic consequence of the supplied Toda note (28) and the frozen companion reader's exterior equality calculation (E8); no novelty claim or Lean execution.

S18.1.1 Original objects and notation

Fix the existing nonempty packet, its tensor degree k , cyclic algebra $C = C[S]/\chi$, $q = \deg \chi$, $A = M_S$, and an admitted degree $N \geq q$. All quantities below are at the original observation $\theta = 0$. Retain G_N , the least-norm quotient Gram, and the adjoint $A^\sharp = G_N^{-1} A^* G_N$. Write $H_N = A^\sharp + A - kI$. Its eigenvalues are $+\epsilon_N$, $-\epsilon_N$, and zero, with the multiplicities from the rank-two calculation.

Let V_+ be the full generalized right-half-plane spectral subspace of A , and P_N its G_N -orthogonal projector. Its positive excess is

$$L = \sum_{\text{Re } \lambda > k/2} \ell_\lambda (2 \text{Re } \lambda - k).$$

Consider the nonempty V_+ case, so $L > 0$ and $\epsilon_N > 0$ by the proved exterior trace bound. Let u_+ , u_- be G_N -unit eigenvectors of H_N at $+\epsilon_N$ and $-\epsilon_N$. The coordinate injection $E_N : C^2 \rightarrow C$ sends (z_+, z_-) to $z_+ u_+ + z_- u_-$. Set $M_N = E_N^\sharp P_N E_N$. Thus $0 \leq M_N \leq I_2$. These eigen-coordinates describe a compression only; they do not replace the arithmetic metric.

Use $C_N = P_N A (1 - P_N) : V_+^\perp \rightarrow V_+$ for the actual off-diagonal coupling. The symbol C_N is used here to avoid confusing this coupling with the Toda note's operator $T = (A - kI/2)/i$. Every Hilbert-Schmidt norm below uses the original restricted G_N metrics.

For the scalar quantities retain

$$V_N = \det G_N = D_{(N+1)}/B_{(N-q+1)}, \quad v_N = \log(V_{(N-1)}/V_N), \quad s_N = (v_N + v_{(N+1)})/2, \quad t_N = (v_{(N+1)} - v_N)/2, \quad a_{(N+1)} = \omega_{(N+1)}/\omega_N, \quad \phi_N = \sigma - \partial_\theta \log V_N|_{\theta=0}, \quad \sigma = \text{Tr}((A - kI/2)/i).$$

Here D and B are exactly the source and relation Hankel determinant sequences in the supplied note, not alternative free sequences.

S18.1.2 Complete loss identity

The Toda identity gives

$$a_{(N+1)} \sinh(s_N)^2 - \epsilon_N^2 = a_{(N+1)} (\exp(t_N) - \cosh(s_N))^2 + \phi_N^2.$$

The companion's E8 gives, on the same original metric,

$$\epsilon_N^2 - L^2 = \|C_N\|_-(HS, G_N)^2 + \epsilon_N^2 (\det M_N + \det(I_2 - M_N)).$$

Adding these equalities cancels precisely ϵ_N^2 and proves

$$a_{(N+1)} \sinh(s_N)^2 - L^2 = a_{(N+1)} (\exp(t_N) - \cosh(s_N))^2 + \phi_N^2 + \|C_N\|_-(HS, G_N)^2 + \epsilon_N^2 (\det M_N + \det(I_2 - M_N)).$$

All four terms on the right are nonnegative. The first two are the successive-volume imbalance and the retained phase. The last two are the original spectral-subspace coupling and the compression remainder. There is no cancellation between them.

The exact Sylvester morphism is also retained. In the G_N -orthogonal decomposition $C = V_+ \text{ plus } V_+^{\perp}$, write $A = [[B_N, C_N], [0, D_N^{\text{op}}]]$, and the CRT spectral idempotent as $Q = [[I, X_N], [0, 0]]$. The identity $AQ = QA$ is exactly

$$B_N X_N - X_N D_N^{\text{op}} = C_N.$$

Its inverse is $\int_0^\infty \exp(-t B_N) Y \exp(t D_N^{\text{op}}) dt$; the strict real spectral separation and the complete finite nilpotent polynomial factors give convergence. Consequently the coupling term controls $\|Q - P_N\|$ by the actual smallest singular value of this Sylvester map, as in E14-E18. No uniform bound for that singular value is inserted here.

S18.1.3 What this adds to the two-step inequality

Let $R_N = V_{(N-1)}/V_{(N+1)} = \exp(2s_N)$. Dropping only the imbalance square and the nonnegative compression remainder gives the stronger finite inequality

$$a_{(N+1)} (R_N - 1)^2 / (4 R_N) \geq L^2 + \phi_N^2 + \|C_N\|_-(HS, G_N)^2.$$

Since $s_N \geq 0$, this is equivalently

$$\log R_N \geq 2 \operatorname{arsinh}(\sqrt{L^2 + \phi_N^2 + \|C_N\|_-(HS, G_N)^2} / \sqrt{a_{(N+1)}}).$$

For a full quartet at zero tilt, the supplied symmetry proves $\phi_N = 0$; the coupling term is still present. If that coupling is nonzero, the original lower bound with L alone is strictly sharpened at that N . Nothing here supplies uniform strictness or large- k decay. The retained endpoint $N = q-1$ uses the source note's separate endpoint formula rather than these preceding-volume ratios.

The empty selected subspace has $L = 0$ and should use the Toda identity directly; no positive-eigenline construction is asserted when $\epsilon_N = 0$.

S18.1.4 Evidence and reading scope

The parent read the complete supplied NOTE.tex, including its sections 1-10, references and explicit first-degree calculation, directly from `Tau_Toda_Volume_Control_2026-09-12.zip` (SHA-256 80b365233ba5ebaf1b52aeea369a7771d74bf774dbb4416f10a56503321b8f41). The companion E8/E14-E18 source is pinned by GitHub commit 161089942cce70a09fbe441d08ba4d36c1fd810c, under `workbenches/splitzero-tandem/continuations/20260912-cyclic/tex/` `exterior_trace_equality_continuation.tex`. The displayed join was checked by literal addition of the two equalities. The independent delivery/checker review is separate in `toda_review/`.

Primary-source context checked in this turn: DLMF 5.11.9 for gamma vertical-strip decay, and DLMF 18.2(ix), especially 18.2.30 and the following numerical-conditioning warning. The supplied 1997 Toda paper was verified at publisher abstract/metadata scope; its full proof was not fetched. These references identify the classical ingredients, not a prior source for this arithmetic specialization.

S19 Gamma convolution descent and the original arithmetic coefficient correction

Source attribution. Complete original Gamma Convolution Descent Markdown note delivered on 13 September 2026. Its archive and alternate complete TeX note are retained byte-for-byte. The full local coefficient chapter proves the exact coordinate maps, finite derivative indices, cochain primitive and transform domains alongside this unmodified source witness. Source reports about remote revisions and computations retain the verification scope of their original receipts.

Exact revision. 886c82e2562d9b4846adb44640d28a34552e38eb2518a3cd47f90dbbedd95e5b

Source file. `sources/web_gamma_convolution_delivery/Tau_Gamma_Convolution_Descent/RESEARCH_NOTE.md`

This appendix reproduces the complete proof note as a dated source witness. Descriptions of what is new, unavailable, or left for continuation refer to that source revision. The current local continuations and their proofs are in Part I. The appendix is attributed to its originating web contribution; it is not presented as a newly discovered local proof.

Formal status. Complete source witness. Finite checker records are separately retained. No new local Lean execution is claimed.

S19.1 1. Scope and the inspected collaboration state

This is a mathematical continuation of **Tau Toda Volume Control** and **Tau Exterior Trace Amplification**. It retains their arithmetic source, quotient, scaling action, full packet multiplicities, and canonical minimum-norm metric. The new calculation links those objects to the gamma reference that is already in the repository. The gamma orthogonal polynomials and their general convolution identities are classical. The contribution here is the explicit arithmetic coefficient transform, its source and quotient maps, its quantitative bounds, and the resulting exact substitution into the existing Toda/exterior estimate.

The GitHub read was pinned to main fa4be32f87a9a90f3c02a07f7790dea95a1e7b0f. The separate formalization was read at PR #22 head 811210d24b80813a08972ca23f919db015383137. At that inspected revision the PR explicitly said strict verification was still in progress. No successful certificate for that revision is inferred here. Its invariant-filtration trace budget is retained as the other session's result, not presented as a new deduction of this note.

The main-branch gamma source read was `workbenches/splitzero-tandem/continuations/20260912-stieltjes/tex/theta_gamma_reference.tex`, equations TG.2–TG.14. It already constructs the exact one-factor gamma measure, its constants, its monic polynomials and its arithmetic multiplier. We extend that specified reference through the sum pushforward at every tensor degree.

There is no new RH proof or arithmetic asymptotic assertion here. Theorems below have written proofs. The checker supplies finite exact regression evidence, not analytic interval certification and not Lean execution. No inherited file or other-session branch is modified.

S19.2 2. The original arithmetic source and its split maps

Retain

$$G(R) = \{\tau_R\} \sqcup \{r^\bullet : r \in R\}, \quad e_R = 0_R^\bullet,$$

with the original maps

$$\begin{array}{ccc} G(\mathbb{Z}) & \xrightarrow{G(j)} & G(\mathbb{C}) \\ p\mathbb{Z} \downarrow & & \downarrow p\mathbb{C} \\ \mathbb{Z} & \xrightarrow{j} & \mathbb{C}. \end{array} \quad (1)$$

The target of the first quotient is infinite. Its structural base is the same absolute pointed base $\mathfrak{b}_\tau$. The supported scalar and the external absorber have not changed.

The source complex is

$$C_+ = [V \xrightarrow{\Theta} \mathcal{B}], \quad Q = \mathcal{B}/\Theta V, \quad D = -x\partial_x,$$

where V consists of the original even Schwartz functions with both original moments zero, and $\mathcal{B}$ has the original rapid decay at both multiplicative ends with all D -derivatives. Keep

$$\Theta\phi(x) = \sum_{n \neq 0} \phi(nx), \quad g(s) = 2\xi(s) = s(s-1)\pi^{-s/2}\Gamma(s/2)\zeta(s).$$

Fix a nonempty finite packet $h(s) = \prod_\rho (s - \rho)^{m_\rho}$ of actual zeros, with every selected order complete. For reflection statements require the same dagger stability as the source. Write

$$v_h = g/h, \quad \mathcal{M}F_h = v_h, \quad w_h(t) = \frac{|v_h(1/2 + it)|^2}{2\pi}, \quad \mu_h = \int w_h(t) dt. \quad (2)$$

The cyclic tensor source and its maps remain

$$\mathcal{V}_{h,k}P = P(D_1 + \cdots + D_k)(F_h^{\otimes k}), \quad C_{h,k} = \mathbb{C}[S]/\chi_{h,k}, \quad A = M_S, \quad (3)$$

$$J^{(k)}\mathcal{V}_{h,k} = \eta_{h,k}\pi_\chi, \quad q^{(k)}\mathcal{V}_{h,k} = \sigma_h^{\otimes k}\eta_{h,k}\pi_\chi,$$

where $S = s_1 + \cdots + s_k$ and $\eta_{h,k}[P] = v_h^{\otimes k}P(A_k)1$, with $v_h = j_h(g/h)$. All local units remain in this map.

At polynomial degree N , the original relation map is

$$M_\chi : \mathcal{P}_{N-q} \longrightarrow \mathcal{P}_N, \quad P \mapsto \chi P, \quad q = \deg \chi, \quad (4)$$

and its image under $\mathcal{V}_{h,k}$ consists of the already constructed theta boundaries. Every norm construction below concerns this same map and its quotient. Its squared-norm weight $|\chi|^2$ does not mean that the next conormal ideal is (χ^2) : that ideal remains the exact pullback of the original I^r .

For $h = 1$, the analytic source (2) still exists, but the finite arithmetic quotient is the zero module. Its split lift has e and τ . No nonzero packet or Gram inverse is inferred from that analytic branch.

S19.3 3. Carry the repository's gamma reference through every tensor power

For a fixed real $\lambda > 0$ define exactly

$$r_\lambda(t) = \frac{|\Gamma(\lambda + it/2)|^2}{2\pi}, \quad d\sigma_\lambda(t) = r_\lambda(t)dt, \quad c_\lambda = 2^{1-2\lambda}\Gamma(2\lambda). \quad (5)$$

The repository proves, by the beta integral and Fourier inversion,

$$\int e^{iyt} d\sigma_\lambda(t) = c_\lambda (\cosh y)^{-2\lambda}. \quad (6)$$

Its factor 2 comes from $t = 2u$ in the beta integral. Thus c_λ , rather than 1, is the mass. Fourier uniqueness for finite measures gives the all-tensor identity

$$r_{\lambda,k} := r_\lambda^{*k} = \kappa_{\lambda,k} r_{k\lambda}, \quad \kappa_{\lambda,k} = \frac{c_\lambda^k}{c_{k\lambda}} = 2^{k-1} \frac{\Gamma(2\lambda)^k}{\Gamma(2k\lambda)}. \quad (7)$$

In particular the mass of the sum measure is c_λ^k . For $\lambda = 1/4$ this reads

$$r_{1/4,k}(u) = \frac{2^{k-1} \pi^{k/2}}{\Gamma(k/2)} \frac{|\Gamma(k/4 + iu/2)|^2}{2\pi}, \quad \int r_{1/4,k} = (2\pi)^{k/2}. \quad (8)$$

The literal coordinate map is $(t_1, \dots, t_k) \mapsto u = \sum_i t_i$; u is not replaced by an average or a rescaled variable. The original arithmetic scaling coordinate is still $S = k/2 + iu$.

For real $|\theta| < \pi/2$, analytic continuation of (6) gives

$$Z_{\lambda,k}^\Gamma(\theta) := \int e^{\theta u} r_{\lambda,k}(u) du = c_\lambda^k (\cos \theta)^{-2k\lambda}. \quad (9)$$

The exponential integrability follows either from the original beta-contour estimate or the gamma vertical-strip bound. This justifies all finite differentiated moment integrals used below.

S19.4 4. The sum projection and its complete polynomial complement

Define actual Hilbert spaces

$$\mathcal{H}_k = L^2(\mathbb{R}^k, \prod_i d\sigma_\lambda(t_i)), \quad \mathcal{H}_\Sigma = L^2(\mathbb{R}, r_{\lambda,k}(u) du).$$

Their isometric inclusion is

$$U_\Sigma : \mathcal{H}_\Sigma \rightarrow \mathcal{H}_k, \quad (U_\Sigma f)(\mathbf{t}) = f(t_1 + \dots + t_k). \quad (10)$$

For $k \geq 2$, its adjoint has the explicit disintegration formula

$$(C_\Sigma F)(u) = \frac{1}{r_{\lambda,k}(u)} \int_{\mathbb{R}^{k-1}} F(t_1, \dots, t_{k-1}, u - \sum_{i < k} t_i) \prod_{i < k} r_\lambda(t_i) r_\lambda(u - \sum_{i < k} t_i) d^{k-1}t. \quad (11)$$

Its denominator is the actual fibre mass. Fubini proves $C_\Sigma U_\Sigma = 1$ and $C_\Sigma = U_\Sigma^*$. For $k = 1$ both maps are the identity. Put $P_\Sigma = U_\Sigma C_\Sigma$ and retain

$$F \mapsto (C_\Sigma F, (1 - P_\Sigma)F), \quad (f, n) \mapsto U_\Sigma f + n. \quad (12)$$

These are inverse Hilbert isometries onto $\mathcal{H}_\Sigma \oplus \ker C_\Sigma$. The second component is not discarded. At each original support label ℓ , their reconstructed maps are $(\ell, F) \mapsto (\ell, C_\Sigma F)$ and $(\ell, F) \mapsto (\ell, (1 - P_\Sigma)F)$. A nonzero normal vector has first image $(\ell, 0)$, while its second image retains that vector. Both maps send external absence to external absence; their paired inverse is still (12). Norm and Gram observations have their actual quadratic types, not the type of a linear quotient: $\text{Gram} : \text{Hom}_\mathbb{C}(E, \mathcal{H}) \rightarrow \text{Herm}(E), R \mapsto R^* R$.

S19.4.1 4.1 Exact action on every product-polynomial degree

Let $b_n^{(\lambda)}(t)$ be the repository's monic gamma polynomial, with

$$\sum_{n \geq 0} \frac{b_n^{(\lambda)}(t)}{n!} z^n = (1 - iz)^{-\lambda + it/2} (1 + iz)^{-\lambda - it/2}.$$

Set $\alpha = 2\lambda$. Its complete norm and recurrence are

$$\|b_n^{(\lambda)}\|^2 = c_\lambda n! (\alpha)_n, \quad b_{n+1}^{(\lambda)} = t b_n^{(\lambda)} - n(n + \alpha - 1) b_{n-1}^{(\lambda)}. \quad (13)$$

The polynomials are not divided by their norms. Multiplying the k generating functions proves the literal addition formula

$$b_n^{(k\lambda)}\left(\sum_i t_i\right) = \sum_{n_1 + \dots + n_k = n} \frac{n!}{\prod_i n_i!} \prod_i b_{n_i}^{(\lambda)}(t_i). \quad (14)$$

For a multi-index $\mathbf{n}$, put $n = \sum_i n_i$. The exact sum projection is

$$C_\Sigma \left(\prod_i b_{n_i}^{(\lambda)}(t_i) \right) = \frac{\prod_i (\alpha)_{n_i}}{(k\alpha)_n} b_n^{(k\lambda)}(u). \quad (15)$$

Proof. Pair the product against (14), in the actual product measure. Orthogonality makes the answer zero unless the sum degree is n , and at degree n the answer is $c_\lambda^k n! \prod_i (\alpha)_{n_i}$. The squared norm of the sum polynomial is $c_\lambda^k n! (k\alpha)_n$. Their quotient gives (15).

These tests identify the whole conditional projection, not merely its finite polynomial moments: the gamma sum measure has exponential moments, so its polynomials are dense in L^2 . To verify that last statement, an L^2 vector orthogonal to all polynomials defines a finite measure whose Fourier transform is analytic on a strip by Cauchy-Schwarz and exponential integrability. All derivatives at zero vanish; analytic uniqueness and uniqueness of Fourier transforms give the zero vector.

The retained normal polynomial is

$$n_{\mathbf{n}} = \prod_i b_{n_i}^{(\lambda)}(t_i) - \frac{\prod_i (\alpha)_{n_i}}{(k\alpha)_n} b_n^{(k\lambda)}\left(\sum_i t_i\right).$$

Its exact squared norm is

$$\|n_{\mathbf{n}}\|^2 = c_\lambda^k \left[\prod_i n_i! (\alpha)_{n_i} - \frac{n! \prod_i (\alpha)_{n_i}^2}{(k\alpha)_n} \right]. \quad (16)$$

Thus every degree, every factorial, and the relative component have an explicit map and norm. This is the classical Meixner-Pollaczek addition mechanism, applied with the source's exact scale and masses; it is not a claim to have discovered a new general family of orthogonal polynomials.

S19.5 5. Insert the complete arithmetic multiplier, not a substituted gamma measure

Define the complex amplitude and its squared modulus by

$$A_{h,\lambda}(t) = \frac{v_h(1/2 + it)}{\Gamma(\lambda + it/2)}, \quad B_{h,\lambda}(t) = |A_{h,\lambda}(t)|^2, \quad w_h = B_{h,\lambda} r_\lambda. \quad (17)$$

The entire quotient g/h supplies values at the selected zeros. No pole is inserted into the multiplier at those locations. The full complex amplitude, not only its modulus, remains in the source comparison

$$P \mapsto \prod_i \frac{\Gamma(\lambda + it_i/2)}{\sqrt{2\pi}} A_{h,\lambda}(t_i) P(k/2 + i \sum_i t_i). \quad (18)$$

This is the original Mellin image of $\mathcal{V}_{h,k}P$.

The scalar multiplier on the sum line is

$$B_{h,\lambda;k} = C_\Sigma(B_{h,\lambda}^{\otimes k}).$$

The exact pushforward identity is

$$\boxed{m_{h,k}(u) = w_h^{*k}(u) = r_{\lambda,k}(u) B_{h,\lambda;k}(u)}. \quad (19)$$

This is a norm observation of the original source; it does not project the original finite arithmetic module or change its trace. The maps in (3), including the full unit in η , remain attached to every polynomial. The full field $B_{h,\lambda}^{\otimes k}$ is recoverable from (12), so its relative complement is retained too.

S19.5.1 5.1 A bounded multiplier for every full quartet

For $\lambda = 1/4$, the original formula is

$$A_{h,1/4}(t) = \frac{-\pi^{-1/4}(t^2 + 1/4)e^{-it \log \pi/2} \zeta(1/2 + it)}{h(1/2 + it)}. \quad (20)$$

The minus sign and phase are still in (18). The elementary continuation formula

$$\zeta(s) = \frac{s}{s-1} - s \int_1^\infty \{x\} x^{-s-1} dx$$

gives, on this line,

$$|\zeta(1/2 + it)| \leq 1 + 2\sqrt{t^2 + 1/4} \leq 2(1 + |t|).$$

Let $d = \deg h \geq 3$ and take $T_h = \max(1, 2 \max_\rho |\rho - 1/2|)$. For $|t| \geq T_h$, $|h(1/2 + it)| \geq (|t|/2)^d$, and direct substitution gives

$$B_{h,1/4}(t) \leq \frac{25 \cdot 2^{2d}}{\sqrt{\pi}} |t|^{6-2d}.$$

Consequently the finite, specified constant

$$C_h = \max \left\{ \sup_{|t| \leq T_h} |A_{h,1/4}(t)|^2, \frac{25 \cdot 2^{2d}}{\sqrt{\pi}} T_h^{6-2d} \right\}$$

satisfies $0 \leq B_{h,1/4} \leq C_h$. The compact supremum uses the analytic quotient, not the expression with a removable denominator left untreated. A full nonreal quartet has $d = 4m \geq 4$, so this applies to the entire packet used in the exterior amplification, with constants allowed to depend on that fixed packet.

The positive integral in (11) now proves

$$\boxed{0 < B_{h,1/4;k}(u) \leq C_h^k \quad (k \geq 2), \quad 0 \leq m_{h,k}(u) \leq C_h^k r_{1/4,k}(u).} \quad (21)$$

Strict positivity for $k \geq 2$ follows because the one-factor multiplier only vanishes at a discrete set; its excluded hyperplanes have zero fibre measure. For $k = 1$ retain its actual isolated zeros.

S19.5.2 5.2 The other packet sizes and the empty analytic source

For a chosen reference below, C_h always denotes an explicitly specified upper bound for that reference's $B_{h,\lambda}$. An explicit alternate reference is available without changing the arithmetic source. For integer $L \geq 0$,

$$A_{h,1/4+L}(t) = \frac{A_{h,1/4}(t)}{\prod_{j=0}^{L-1} (j + 1/4 + it/2)}. \quad (22)$$

Its product is a known nonvanishing gamma-shift factor on the integration line. Taking $L \geq \max(0, 3 - d)$ makes its squared modulus bounded by the same compact/tail argument. Equations (17)–(19) connect both references to the identical original w_h ; no coordinate or original mass is reassigned.

For the actual seed $h = 1$, choosing $L = 3$ gives the explicit all-real estimate

$$\boxed{B_{1,13/4}(t) \leq 1024/\sqrt{\pi}.} \quad (23)$$

Indeed the gamma-shift denominator is $4^{-3}(t^2 + 1/4)(t^2 + 25/4)(t^2 + 81/4)$, and $|\zeta(1/2 + it)| \leq 4\sqrt{t^2 + 1/4}$. The remaining fraction is bounded by one since $(t^2 + 1/4)^2 \leq (t^2 + 25/4)(t^2 + 81/4)$.

This is an analytic estimate for a nonzero seed. Its finite spectral quotient is still zero, as required by the merged correction.

S19.6 6. Exact arithmetic coefficients at every tensor degree

Use a reference for which $B = B_{h,\lambda}$ is bounded, as constructed above. Define its actual coefficients

$$c_{h,j} = \frac{\int b_j^{(\lambda)}(t) w_h(t) dt}{c_\lambda j! (\alpha)_j}, \quad \mathcal{A}_h(z) = \sum_{j \geq 0} (\alpha)_j c_{h,j} z^j. \quad (24)$$

The series is used coefficientwise; no convergence radius for this formal series is stipulated. Each coefficient is an actual one-factor arithmetic integral. Define

$$d_{h,k,n} = [z^n] \mathcal{A}_h(z)^k.$$

Then the complete $L^2(r_{\lambda,k} du)$ expansion is

$$\boxed{B_{h,\lambda;k}(u) = \sum_{n \geq 0} \frac{d_{h,k,n}}{(k\alpha)_n} b_n^{(k\lambda)}(u).} \quad (25)$$

Proof. Pair $B^{\otimes k}$ with the finite addition formula (14). Each one-factor pairing is $c_\lambda j! (\alpha)_j c_{h,j}$. The multinomial coefficient cancels the displayed factorials and gives

$$\int B_{h,\lambda;k} b_n^{(k\lambda)} r_{\lambda,k} = c_\lambda^n n! [z^n] \mathcal{A}_h(z)^k.$$

Divide by the exact norm $c_\lambda^k n! (k\alpha)_n$. Completeness gives (25). No exchange of an infinite product of formal series with an integral was needed: every coefficient used a finite polynomial identity.

At degree zero,

$$c_{h,0} = \mu_h / c_\lambda, \quad d_{h,k,0} = (\mu_h / c_\lambda)^k,$$

so (25) recovers exactly $\int m_{h,k} = \mu_h^k$.

The retained relative residual is

$$\mathcal{N}_{h,k} = B^{\otimes k} - U_\Sigma B_{h,\lambda;k}.$$

Its whole norm is calculated by Pythagoras:

$$\|\mathcal{N}_{h,k}\|^2 = \left(\int B(t)^2 d\sigma_\lambda(t) \right)^k - c_\lambda^k \sum_{n \geq 0} \frac{n!}{(k\alpha)_n} |d_{h,k,n}|^2. \quad (26)$$

The difference is nonnegative because it is the norm of the explicitly retained vector. It is not set to zero by calling the sum map a pushforward.

S19.6.1 6.1 Finite exactness and approximation errors

Let $B_L = \sum_{j=0}^L c_{h,j} b_j^{(\lambda)}$ and $B_{k,L} = C_\Sigma(B_L^{\otimes k})$. Projection contraction and the tensor telescoping identity give

$$\|B_{h,\lambda;k} - B_{k,L}\| \leq k \|B\|^{k-1} \|B - B_L\|. \quad (27)$$

These norms have the respective original reference measures. The proof uses $\|B_L\| \leq \|B\|$ and expands the tensor difference into k terms. Both sides retain the full mass factors.

More strongly, the moments of $B_{k,L} r_{\lambda,k}$ against every polynomial of degree at most L are **exactly** those of $m_{h,k}$, since coefficient $n \leq L$ in (25) uses only $c_{h,j}$ with $j \leq n$.

It follows that the entire degree- N source Gram, and its degree- N relation Gram, are determined exactly by $c_{h,0}, \dots, c_{h,2N}$. The relation integrands are also degree at most $2N$. Their tensor dependence is the explicit finite coefficient power in (24), not a fresh k -dimensional integral.

A truncated $B_{k,L}$ need not be nonnegative pointwise. Its relationship to the true positive metric is the exact finite-moment equality just proved when $L \geq 2N$, or the error estimate (27) and Cauchy-Schwarz for the specified polynomial tests when $L < 2N$. Positivity is not inferred from a plotted truncated density.

S19.6.2 6.2 Actual seed coefficients, and their tensor cross term

The supplied numerical driver evaluates the original theta seed on $x \geq 1$, using its inversion symmetry. With $L = D - 1/2$, the even spectral moments are $\mu_{2r} = 2 \int_1^\infty |L^r f_0(x)|^2 dx$. It constructs their source polynomials by $q_0(z) = 4z^2 - 6z$ and $q_{r+1} = 2z(q_r - q'_r) - q_r/2$, and integrates the integer double sums using upper incomplete gamma integrals. This is a numerical check, not a validated interval computation.

For $h = 1$ and the bounded-multiplier reference $\lambda = 13/4$, the 50-digit, cutoff-6 and 70-digit, cutoff-8 calculations agree in the displayed values:

Quantity	Numerical value
μ_0	1.279007247846485140479533592267
μ_2	13.055549302570558435392684658123
μ_4	383.274341717364242554407237479131
μ_6	17946.5273016052076235667646919834
$c_{h,0}$	0.201056688692785865809916163220
$c_{h,2}$	0.007645442999486401188133851481
$c_{h,4}$	-0.000030516920803762043746724840

The reference mass is $c_{13/4} = 6.361426004587219292629853548733 \dots$, so it has not been assigned the actual mass μ_0 or the value one. The negative fourth expansion coefficient is retained; a positive density need not have positive coefficients in this orthogonal basis.

For every even arithmetic multiplier, the first tensor terms from (25) are exactly

$$d_{h,k,2} = k c_{h,0}^{k-1}(\alpha)_2 c_{h,2},$$

$$d_{h,k,4} = k c_{h,0}^{k-1}(\alpha)_4 c_{h,4} + \binom{k}{2} c_{h,0}^{k-2}((\alpha)_2 c_{h,2})^2.$$

Both terms in the fourth coefficient remain. These are coefficients of the exact arithmetic source norm; the empty packet still supplies no nonzero finite spectral quotient. Agreement of two numerical truncations is not a bound on their shared truncation or rounding error.

S19.7 7. Feed the result into the two original Toda determinants

Put $\alpha_k = 2k\lambda$. The full gamma source determinants are explicit:

$$\mathfrak{D}_n^\Gamma(\theta) = c_\lambda^{kn} \prod_{j=0}^{n-1} j! (\alpha_k)_j (\cos \theta)^{-n(\alpha_k+n-1)}. \quad (28)$$

At $\theta = 0$ this is the product of the monic norms from (13) and (7). One direct proof for all real θ starts with $\mathfrak{D}_0^\Gamma = 1$ and $\mathfrak{D}_1^\Gamma = c_\lambda^k \cos^{-\alpha_k} \theta$. Apply the already-proved Hankel-Toda identity recursively; the second derivative of the logarithm of the right side is $n(\alpha_k + n - 1) \sec^2 \theta$. Substitution proves the next determinant with all constants. Strict positivity makes the recurrence division valid.

In particular

$$\omega_n^\Gamma(\theta) = c_\lambda^k n! (\alpha_k)_n (\cos \theta)^{-(\alpha_k+2n)}, \quad a_n^\Gamma(\theta) = n(n + \alpha_k - 1) \sec^2 \theta. \quad (29)$$

The arithmetic source determinant is the previous $\mathfrak{D}_n$. The reference relation determinant is

$$\mathfrak{B}_n^\Gamma(\theta) = \det \left[\partial_\theta^{i+j} \left\{ \bar{\chi}(k/2 - i\partial_\theta) \chi(k/2 + i\partial_\theta) Z_{\lambda,k}^\Gamma(\theta) \right\} \right]_{i,j < n}. \quad (30)$$

It is the Gram of the **same** multiplication map M_χ . This is an explicit finite expression in gamma constants, $\cos \theta$, $\tan \theta$, and the original coefficients of χ .

Define positive scalar corrections, including the empty-index value one,

$$X_n = \mathfrak{D}_n / \mathfrak{D}_n^\Gamma, \quad Y_n = \mathfrak{B}_n / \mathfrak{B}_n^\Gamma.$$

The source-boundary determinant theorem now factors as

$$\boxed{V_N = V_N^\Gamma T_N, \quad V_N^\Gamma = \frac{\mathfrak{D}_{N+1}^\Gamma}{\mathfrak{B}_{N-q+1}^\Gamma}, \quad T_N = \frac{X_{N+1}}{Y_{N-q+1}}.} \quad (31)$$

This retains the entire arithmetic correction in both numerator and denominator. It is not an assertion that the arithmetic quotient metric equals the reference metric.

S19.7.1 7.1 The representative map between the two metrics

Use the same finite polynomial source. Let B_χ be the injective matrix of its original relation columns, and let R_N^Γ be the least-norm lift for the gamma observation. Let M_h be the actual arithmetic source Gram. Then the actual lift is

$$\boxed{R_N = R_N^\Gamma - B_\chi (B_\chi^* M_h B_\chi)^{-1} B_\chi^* M_h R_N^\Gamma.} \quad (32)$$

For an empty boundary block the correction is the zero map. The proof is direct: the correction is an old relation, so the quotient remains the identity; multiplication by $B_\chi^* M_h$ gives zero. These two properties characterize the arithmetic least-norm lift.

Applying $\mathcal{V}_{h,k}$ to (32) supplies the original theta primitive of the difference. In the reconstructed support carrier, the difference maps to the supported zero in its fibre. It does not disappear from the source metric or from its boundary primitive. The comparison keeps the complete unit in (3).

S19.7.2 7.2 A genuine source-side upper bound

From (21), for every admitted polynomial,

$$\|P\|_h^2 \leq C_h^k \|P\|_\Gamma^2.$$

Evaluate this inequality on $R_N^\Gamma u$ and then minimize on the arithmetic side. This proves

$$\boxed{G_N \preceq C_h^k G_N^\Gamma, \quad 0 < T_N \leq C_h^{kq}.} \quad (33)$$

The second assertion is the determinant inequality in dimension q . It has the quotient dimension, rather than the full polynomial-source dimension, in its exponent. The corresponding source estimate is $0 < X_n \leq C_h^{kn}$, and similarly $0 < Y_n \leq C_h^{kn}$.

These are one-sided estimates. They do not bound the consecutive ratio T_{N-1}/T_{N+1} , which is the quantity required by the Toda upper bound. Its exact map to that estimate is the following.

S19.8 8. The current upper-control expression, with all reference costs exposed

Define

$$Q_N = \frac{X_{N+2} X_N}{X_{N+1}^2}, \quad \mathcal{R}_N^\Gamma = \frac{V_{N-1}^\Gamma}{V_{N+1}^\Gamma}.$$

At the original observation $\theta = 0$, (29)–(31) give

$$\boxed{a_{N+1} = (N+1)(N+\alpha_k)Q_N, \quad \mathcal{R}_N = \mathcal{R}_N^\Gamma \frac{T_{N-1}}{T_{N+1}}.} \quad (34)$$

The preceding exact phase identity is also retained through

$$\ell'_N = \partial_\theta \log V_N^\Gamma + \partial_\theta \log T_N.$$

Thus its finite upper bound becomes exactly

$$\epsilon_{h,k,N} \leq \sqrt{(N+1)(N+\alpha_k)Q_N} \frac{\mathcal{R}_N^\Gamma T_{N-1}/T_{N+1} - 1}{2\sqrt{\mathcal{R}_N^\Gamma T_{N-1}/T_{N+1}}}. \quad (35)$$

The nonnegative numerator uses the original monotonicity of the actual quotient minimum, not a presumed monotonicity of T_N . When this inequality is coarse, the inherited equality with the volume-imbalance square and the phase square remains the sharper calculation.

For the full quartet one can keep $\lambda = 1/4$, so $\alpha_k = k/2$. The gamma source recurrence is now explicit at every degree; the remaining arithmetic dependence is in Q_N and the relative source-boundary correction T_{N-1}/T_{N+1} . The reference relation term still contains the full spectral annihilator χ . It is not bounded by pretending its roots are on the integration line.

The exterior theorem remains

$$L_{h,k} \leq \epsilon_{h,k,N}, \quad L_{h,k} = 2\delta[1 + k(m-1)](k+1) \left\lfloor \frac{(k+1)^2}{4} \right\rfloor.$$

Neither (33) nor (35) proves a subcubic bound. Equation (35) identifies exactly which degree-to-degree arithmetic corrections must be controlled next. All entries of those finite determinants can now be generated by the all- k coefficient transform (25), with the source-boundary comparison map (32) retained.

S19.9 9. A proved all-degree tail estimate for the actual arithmetic moments

The multiplier bound gives more than a change of coordinates. For $a, b > 0$ with $a + b < \pi/2$, every integer $r \geq 0$ and $T \geq 0$,

$$\int_{|u|>T} |u|^r m_{h,k}(u) du \leq 2C_h^k c_\lambda^k r! a^{-r} e^{-bT} (\cos(a+b))^{-2k\lambda}. \quad (36)$$

Proof. For $x \geq 0$, $x^r \leq r! a^{-r} e^{ax}$. On the indicated tail, $1 \leq e^{b(x-T)}$. Apply (21) and integrate. Since the reference density is even,

$$\int e^{(a+b)|u|} r_{\lambda,k}(u) du \leq Z_{\lambda,k}^\Gamma(a+b) + Z_{\lambda,k}^\Gamma(-a-b).$$

Equation (9) gives (36). This estimate retains the original mass and the complete tensor cost. It is a theorem with specified constants, not a claim that a floating-point quadrature has validated them numerically.

For a source or relation moment whose integrand is a polynomial $P(u) = \sum_j p_j u^j$, sum $|p_j|$ times (36). In particular this controls every entry of a degree- N source and relation Gram, including the full $|\chi|^2$ factor. It is then combined with an independently certified compact-interval quadrature and the existing matrix inverse/error inequalities; it does not certify that quadrature by itself.

This is an explicit tail interface for the actual arithmetic input at all degrees and tensor powers. For the empty analytic seed, (23) gives a completely stated bound without locating any zeta zero. For a nonempty packet the compact constant in C_h must be enclosed using the actual analytic quotient.

S19.10 10. What has and has not been concluded

The constructed chain is

- original split-supported polynomial source
- full gamma product fibre with arithmetic amplitude
- sum density and retained relative component
- exact all-tensor arithmetic coefficients
- the same source–boundary Toda determinant ratio.

The finite coefficient projection, polynomial degree, all masses, all gamma factors, the arithmetic unit, and the original theta primitives are explicit. The same finite quotient is used throughout; an existing relation becomes e only under its original quotient map, while the source norm and all derivative data remain available before that map. No new scalar-zero adjunction is performed at a tensor or relation level.

There is now a proved bound for the full arithmetic sum density, explicit closed-form reference determinants at every tensor degree, an exact finite coefficient algorithm, and a rigorous moment-tail bound. There is not yet a uniform small bound for the consecutive arithmetic determinant correction. The upper-estimate problem is sharpened to that specific comparison rather than being claimed solved by gamma convolution or by positivity of individual source Grams.

A uniform polynomial-norm estimate; integration with the four-volume criterion

Source metadata: title (MetaInlines)

Arithmetic endpoint bounds on the original τ -base source

S20.1 1. Result and exact source boundary

The formalization session's endpoint criterion selects an actual member of the canonical arithmetic family. This continuation proves one of its previously unproved analytic inputs. For the **unchanged arithmetic measure**, a fixed finite packet h , and integers $n \geq k \geq 3$, there is a finite constant C_h , independent of n and k , such that

$$\left(\frac{\omega_{h,k,2n}}{\omega_{h,k,n}} \right)^{1/(2n)} \leq C_h n. \quad (1)$$

The norms are the original monic polynomial norms for $m_{h,k} = w_h^{*k}$; the total mass remains μ_h^k . No root-location hypothesis is used in this bound. The proof retains a compact-source mass, a lower convolution constant, and both exponential moments. These constants are defined explicitly below; they have not been numerically enclosed.

For the packet consisting exactly of a hypothetical nonreal off-line quartet, let

$$q_k = [1 + k(m-1)](k+1)^2, \quad L_{h,k} = 2\delta[1 + k(m-1)](k+1) \left\lfloor \frac{(k+1)^2}{4} \right\rfloor. \quad (2)$$

The existing exterior theorem gives $L_{h,k} \leq \epsilon_{h,k,N}$ at every admitted degree. Combining (1) with the other session's endpoint theorem gives

$$\min_{q_k \leq N < 2q_k} \epsilon_{h,k,N} \leq C_h q_k \sinh\left(\frac{\mathcal{B}_{h,k}}{2q_k}\right), \quad \mathcal{B}_{h,k} = \log \frac{V_{q_k-1} V_{q_k}}{V_{2q_k-1} V_{2q_k}}. \quad (3)$$

Consequently such a quartet forces

$$\mathcal{B}_{h,k} \geq 2q_k \operatorname{arsinh}\left(\frac{\delta k}{2C_h}\right), \quad \liminf_{k \rightarrow \infty} \frac{\mathcal{B}_{h,k}}{q_k \log k} \geq 2. \quad (4)$$

The upper bound for this four-volume quantity is not proved here. In particular, (1) does not establish RH. It completes the polynomial-norm input in (3) on a specific admissible window and leaves the source/relation-volume comparison with its exact maps. Section 9 expresses that remaining quantity as two positive block log-determinants of actual new relation layers.

The finite quotient, canonical source, residue action and rank-two control are inputs from the preceding analytic notes. The new proofs in Sections 3–7 use only their explicitly defined arithmetic measure. The endpoint theorem is the formalizer's written result, not attributed to this continuation. Its finite telescopes are reported kernel-checked; the analytic estimates below have written proofs, not new Lean certificates.

S20.2 2. The base, source, and both kinds of quotient

Retain the original marked coefficient square

$$\begin{array}{ccc} G(\mathbb{Z}) & \xrightarrow{G(j)} & G(\mathbb{C}) \\ p_{\mathbb{Z}} \downarrow & & \downarrow p_{\mathbb{C}} \\ \mathbb{Z} & \xrightarrow{j} & \mathbb{C}. \end{array} \quad (5)$$

Here $G(R) = \{\tau\} \sqcup \{r^\bullet : r \in R\}$, $e_R = 0_R^\bullet$, $p_R(\tau) = 0_R$, and $p_R(r^\bullet) = r$. The target of $p_{\mathbb{Z}}$ is infinite. The construction remains over the original pointed base $\mathfrak{b}_\tau$; no new scalar zero is adjoined at a tensor degree or at a polynomial relation layer.

Keep $C_+ = [V \xrightarrow{\Theta} \mathcal{B}]$ in degrees 0, 1, $Q = \mathcal{B}/\Theta V$, and $D = -x\partial_x$. The source spaces and the Fourier transform remain those of the earlier theta construction. In particular,

$$g(s) = 2\xi(s) = s(s-1)\pi^{-s/2}\Gamma(s/2)\zeta(s), \quad \mathcal{M}\Theta\phi_* = g. \quad (6)$$

Let h be a fixed finite product of zeros of g , with the full order of each selected zero retained, and write $d = \deg h$. Define

$$v_h = g/h, \quad w_h(t) = \frac{|v_h(1/2 + it)|^2}{2\pi}, \quad \mu_h = \int_{\mathbb{R}} w_h(t) dt, \quad m_{h,k} = w_h^{*k}. \quad (7)$$

The quotient v_h is entire, including at the selected centres. It is not the meromorphic expression evaluated before removing its actual removable factors. For $h = 1$, the same analytic definitions are meaningful, but the finite arithmetic packet is zero. Only the nonempty case is used for the finite Gram inverses below.

The source map is

$$\mathcal{V}_{h,k} : \mathbb{C}[S] \longrightarrow \mathcal{B}^{\widehat{\otimes} k}, \quad P \longmapsto P(D_1 + \cdots + D_k)(F_h^{\otimes k}), \quad \mathcal{M}F_h = v_h. \quad (8)$$

The original cyclic module is $E_{h,k} = \mathbb{C}[S]/(\chi_{h,k})$. Its arithmetic inclusion keeps the Taylor unit:

$$\eta_{h,k}[P] = v_h^{\otimes k} P(A_k)1, \quad v_h = j_h(g/h), \quad A_k = \sum_i M_{s_i}. \quad (9)$$

The supplied source identities are

$$J^{(k)}\mathcal{V}_{h,k} = \eta_{h,k}\pi_\chi, \quad q^{(k)}\mathcal{V}_{h,k} = \sigma_h^{\otimes k}\eta_{h,k}\pi_\chi. \quad (10)$$

The actual norm of (8) is

$$\|\mathcal{V}_{h,k}P\|^2 = \int_{\mathbb{R}} |P(k/2 + iu)|^2 m_{h,k}(u) du. \quad (11)$$

For $\mathcal{P}_n = \mathbb{C}[S]_{\leq n}$, the monic norm is the quotient norm of the leading-coefficient map

$$0 \longrightarrow \mathcal{P}_{n-1} \longrightarrow \mathcal{P}_n \xrightarrow{\text{lc}_n} \mathbb{C} \longrightarrow 0, \quad \omega_{h,k,n} = \inf_{\text{lc}_n} \|\mathcal{V}_{h,k}P\|^2. \quad (12)$$

The arithmetic quotient is the other specified map from the same source:

$$0 \longrightarrow \mathcal{P}_{n-q} \xrightarrow{\times\chi} \mathcal{P}_n \xrightarrow{\pi_\chi} E_{h,k} \longrightarrow 0, \quad q = \deg \chi, \quad (13)$$

for $n \geq q - 1$, with the preceding relation space zero at $n = q - 1$. Multiplication by the monic χ carries $\mathcal{P}_{n-q}/\mathcal{P}_{n-q-1}$ isomorphically to $\mathcal{P}_n/\mathcal{P}_{n-1}$, with leading coefficient unchanged. The map π_χ kills that very relation. Thus (12), (13), and multiplication by χ specify the relation between the degree-line norm and the arithmetic quotient metric. One norm is not substituted for the other.

At each admitted original support label λ , the lifted quotient is $(\lambda, P) \mapsto (\lambda, [P]_\chi)$. An original relation has image $(\lambda, 0)$; external absence has image τ . Its norm before this projection remains available through (11).

S20.3 3. A quantitative local arithmetic mass lemma

S20.3.1 3.1 Uniform polynomial growth on a fixed strip

There is a constant $C_0 \geq 1$ such that, for $|T| \geq 10$, the function

$$f_T(z) = \zeta(1/2 + iT + iz) \quad (14)$$

is holomorphic on and inside the ellipse

$$z = \frac{1}{2}(w + w^{-1}), \quad |w| = 8, \quad (15)$$

and has modulus at most $M_T = C_0(1 + |T|)^6$ there.

The ellipse has real and imaginary semiaxes $65/16$ and $63/16$. Hence its image in the s -plane lies in $-55/16 \leq \Re s \leq 71/16$ and $|\Im s - T| \leq 65/16$. The pole of ζ is outside this set when $|T| \geq 10$.

For $\Re s \geq 1/4$, use the identity

$$\zeta(s) = \frac{s}{s-1} - s \int_1^\infty \{x\} x^{-s-1} dx. \quad (16)$$

It follows by summing the steps of $\lfloor x \rfloor$ for $\Re s > 1$ and then by analytic continuation for $\Re s > 0$, $s \neq 1$. Its integral is bounded by $1/\Re s$, giving $O(1 + |T|)$ on the indicated part of the ellipse. For $\Re s \leq 1/4$, the functional equation

$$\zeta(s) = 2^s \pi^{s-1} \sin(\pi s/2) \Gamma(1-s) \zeta(1-s) \quad (17)$$

and the vertical-strip gamma estimate give $O((1 + |T|)^{3/2 - \Re s})$. On the stated strip this exponent is below 5. The common power 6 in (14) is therefore a valid upper bound with one fixed constant. The gamma estimate and functional equation are the classical inputs recorded in DLMF §§5.11 and 25.4; none assumes RH.

Every disc of radius one about a point of $[-1, 1]$ lies inside the ellipse. The maximum principle and Cauchy's derivative formula therefore also give

$$\sup_{x \in [-1, 1]} |f'_T(x)| \leq M_T. \quad (18)$$

S20.3.2 3.2 Propagate a nonzero value to the critical-line interval

Put

$$r_* = (3 + \sqrt{13})/2 < 4, \quad z_* = -3i/2 = \frac{1}{2}(-ir_* + (-ir_*)^{-1}), \quad c_* = \zeta(2)^{-1}. \quad (19)$$

The absolutely convergent reciprocal Dirichlet series gives $|1/\zeta(2 + iT)| \leq \zeta(2)$, so $|f_T(z_*)| \geq c_* > 0$. Let $m_T = \max_{[-1, 1]} |f_T|$.

Apply the maximum principle on $1 \leq |w| \leq 8$ to $f_T((w + w^{-1})/2)$. Equivalently subtract from its logarithmic modulus the harmonic function linear in $\log |w|$ with boundary values $\log m_T$ and $\log M_T$. Zeros are handled by the usual subharmonic maximum principle. At $w = -ir_*$ this gives

$$c_* \leq m_T^\vartheta M_T^{1-\vartheta}, \quad \vartheta = 1 - \frac{\log r_*}{\log 8} > \frac{1}{3}. \quad (20)$$

Here $0 < c_* < 1$ and $M_T \geq 1$. Consequently

$$m_T \geq c_*^3 M_T^{-2}. \quad (21)$$

This is the three-circles argument with every coordinate map and radius fixed. No polynomial approximation to ζ or assumption about its zeros is used.

Choose a point attaining m_T . By (18), on a one-sided subinterval of length $m_T/(2M_T) \leq 1/2$ inside $[-1, 1]$, the modulus is at least $m_T/2$. Thus

$$\int_{T-1}^{T+1} |\zeta(1/2 + it)|^2 dt \geq \frac{m_T^3}{8M_T} \geq \frac{c_*^9}{8C_0^7} (1 + |T|)^{-42}. \quad (22)$$

For $T \in [-10, 10]$, the integral in (22) is continuous and strictly positive: otherwise ζ would vanish on an interval and hence identically on its holomorphic domain. Its minimum on that compact interval is positive. Combining it with (22) proves the all-real statement

$$\boxed{\exists c_\zeta > 0 \quad \int_{T-1}^{T+1} |\zeta(1/2 + it)|^2 dt \geq c_\zeta (1 + |T|)^{-42} \quad (T \in \mathbb{R}).} \quad (23)$$

The exponent 42 is deliberately an explicit sufficient exponent, not an optimal local mean-square estimate. The proof is a classical analytic propagation argument specialized here to the needed arithmetic interval.

S20.4 4. A lower envelope for the actual convolution, after three factors

S20.4.1 4.1 Local mass of the unchanged g/h

The gamma estimate, with a positive lower constant valid also on compact sets, implies

$$|\Gamma(1/4 + it/2)|^2 \geq c_\Gamma (1 + |t|)^{-1/2} e^{-\pi|t|/2}. \quad (24)$$

Let $H_h = \prod_{\rho \in Z} (1 + |\rho - 1/2|)^{m_\rho}$, so $|h(1/2 + it)| \leq H_h (1 + |t|)^d$. The entire identity $g = hv_h$ makes this bound valid at selected centres as well: $|g| \leq H_h (1 + |t|)^d |v_h|$. The factors in (6), including $|s(s-1)|^2 = (t^2 + 1/4)^2$, then give a positive constant $c_h^{(0)}$ with

$$w_h(t) \geq c_h^{(0)} e^{-\alpha_0|t|} (1 + |t|)^{-2d} |\zeta(1/2 + it)|^2, \quad \alpha_0 = \pi/2. \quad (25)$$

Equation (25) is a weaker bound than the available factor $(1 + |t|)^{7/2-2d}$; it follows by an inequality, not by changing the density. On $[T-1, T+1]$, its exponential and polynomial weights are bounded below by $e^{-\alpha_0} e^{-\alpha_0|T|}$ and $2^{-2d} (1 + |T|)^{-2d}$, respectively. Hence (23) proves

$$\int_{T-1}^{T+1} w_h(t) dt \geq c_h^{(1)} e^{-\alpha_0|T|} (1 + |T|)^{-B_h}, \quad B_h = 42 + 2d. \quad (26)$$

S20.4.2 4.2 The positive compact convolution factor

The function w_h is continuous, bounded, integrable, and positive outside a discrete set. Thus $m_{h,2} = w_h * w_h$ is continuous and strictly positive at every real point. Indeed its integrand is positive almost everywhere; continuity follows from translation continuity in L^1 and boundedness of the other factor. Define the **actual** compact quantities

$$b_h = \min_{|v| \leq 1} m_{h,2}(v) > 0, \quad \vartheta_h = \int_{-1}^1 w_h(v) dv > 0. \quad (27)$$

Both are determined by the original density; neither is assigned the value one. Restricting a nonnegative convolution integral gives

$$m_{h,3}(u) \geq b_h \int_{u-1}^{u+1} w_h(t) dt \geq c_h e^{-\alpha_0|u|} (1 + |u|)^{-B_h}, \quad c_h = b_h c_h^{(1)} > 0. \quad (28)$$

The omitted part is the nonnegative integral over $|v| > 1$ and remains part of $m_{h,3}$. We use a lower bound, not a new compactly supported density.

For $k \geq 3$, restrict the remaining $k-3$ variables to $[-1, 1]$ and use (28). Their sum has absolute value at most $k-3$. This gives the central analytic estimate

$$\boxed{m_{h,k}(u) \geq c_h \vartheta_h^{k-3} e^{-\alpha_0(|u|+k-3)} (1 + |u| + k - 3)^{-B_h} \quad (k \geq 3, u \in \mathbb{R}).} \quad (29)$$

All mass and tensor factors are explicit. For $k = 3$ the factor ϑ_h^0 is the empty product. No statement for $k = 1, 2$ is inferred by using a negative exponent. The amplification below only needs $k \geq 3$.

S20.5 5. Upper moments and exact lower monic norms

Fix $0 < b < \pi/2$ and retain both one-factor Laplace values

$$M_h(\pm b) = \int e^{\pm bt} w_h(t) dt > 0. \quad (30)$$

They are finite by the original gamma decay. Fubini and positivity give

$$\int e^{b|u|} m_{h,k}(u) du \leq M_h(b)^k + M_h(-b)^k. \quad (31)$$

The elementary exponential-series inequality $x^j \leq j! b^{-j} e^{bx}$ for $x \geq 0$ yields

$$\omega_{h,k,j} \leq (2j)! b^{-2j} (M_h(b)^k + M_h(-b)^k). \quad (32)$$

The trial polynomial is $(S - k/2)^j$, whose value on $S = k/2 + iu$ is $i^j u^j$. Its phase has modulus one and remains in the source map; the generator $A = M_S$ has not been shifted to define a different spectral problem.

For every leading coefficient of modulus one, the exact least squared norm of a degree- j polynomial on $[-L, L]$ with Lebesgue measure is

$$\mathfrak{l}_j(L) = \frac{2L^{2j+1}}{2j+1} \left(\frac{2^j (j!)^2}{(2j)!} \right)^2. \quad (33)$$

To check all constants, Rodrigues' formula gives the Legendre polynomial $P_j(x)$ with leading coefficient $(2j)!/(2^j (j!)^2)$ and squared norm $2/(2j+1)$. Its scaled monic version on $[-L, L]$ is the unique minimizer: subtract it from any competing monic polynomial, and the difference has lower degree and is orthogonal to it. For the source coordinate $S = k/2 + iu$, multiply this minimizer by the retained leading phase i^j . This proves (33) at the original type. See also DLMF §§18.3 and 18.5.

Restricting (11) to $[-L, L]$ and using (29) proves

$$\omega_{h,k,j} \geq c_h \vartheta_h^{k-3} e^{-\alpha_0(L+k-3)} (1+L+k-3)^{-B_h} \mathfrak{l}_j(L) \quad (k \geq 3, L > 0). \quad (34)$$

The observation has the explicit isometric splitting into the inside and outside interval components. Addition recovers the full source function, and their squared norms add. In the split lift each zero component is the supported zero at its label. The outside component has not been declared absent.

S20.6 6. The norm-window estimate is proved

Set $j = n$ and $L = n$ in (34), and use $j = 2n$ in (32). The exact finite bound is

$$\left(\frac{\omega_{h,k,2n}}{\omega_{h,k,n}} \right)^{1/(2n)} \leq \left[\frac{(4n)! b^{-4n} (M_h(b)^k + M_h(-b)^k) e^{\alpha_0(n+k-3)} (1+n+k-3)^{B_h}}{c_h \vartheta_h^{k-3} \mathfrak{l}_n(n)} \right]^{1/(2n)}. \quad (35)$$

For $n \geq k \geq 3$, this is at most $C_h n$. Here is one explicit sufficient constant, with $M_* = \max\{1, M_h(b), M_h(-b)\}$:

$$C_h = 64b^{-2} \exp(\alpha_0) 2^{B_h/2} \exp\left(\frac{B_h}{2 \exp(1)}\right) \sqrt{M_* \max(1, c_h^{-1}) \max(1, \vartheta_h^{-1})}. \quad (36)$$

Proof of the uniform estimate: $\binom{2n}{n} \leq 4^n$ in (33) gives $\mathfrak{l}_n(n) \geq 2n^{2n+1}/((2n+1)4^n)$. Also $(4n)! \leq (4n)^{4n}$, $M_h(b)^k + M_h(-b)^k \leq 2M_*^k$, $n+k-3 \leq 2n$, and $1+n+k-3 \leq 2n$. After taking the $2n$ -th root the factorial and monic factors contribute at most $64n$. The mass factors contribute at most the square root

in (36); the exponential contributes at most $\exp(\alpha_0)$. Finally $n^{1/n} \leq \exp(1/\exp(1))$ gives $(2n)^{B_h/(2n)} \leq 2^{B_h/2} \exp(B_h/(2\exp(1)))$. This proves (1).

The constant is intentionally not optimized. Its dependence on the fixed packet is allowed; its independence of the polynomial and tensor degrees is what is needed. Defining it via positive compact minima does not claim to have provided a numerical interval enclosure for those minima.

For a general source window the same two inequalities give, without asymptotic notation,

$$\left(\frac{\omega_{h,k,n+r}}{\omega_{h,k,n}} \right)^{1/(2r)} \leq \left[\frac{(2(n+r))! b^{-2(n+r)} (M_h(b))^k + M_h(-b)^k e^{\alpha_0(L+k-3)} (1+L+k-3)^{B_h}}{c_h \vartheta_h^{k-3} \mathfrak{l}_n(L)} \right]^{1/(2r)}. \quad (37)$$

S20.7 7. Compose the proved bound with the formalizer's endpoint theorem

For a nonempty cyclic packet $E_{h,k}$, let G_N be its original canonical quotient metric, $V_N = \det G_N > 0$, and $\epsilon_{h,k,N}$ the original rank-two control allowance. The new endpoint theorem supplied by PR #23 is

$$\min_{0 \leq j < r} \epsilon_{h,k,n+j} \leq \left(\frac{\omega_{h,k,n+r}}{\omega_{h,k,n}} \right)^{1/(2r)} \sinh \left(\frac{1}{2r} \log \frac{V_{n-1} V_n}{V_{n+r-1} V_{n+r}} \right), \quad n \geq q. \quad (38)$$

Its proof multiplies the local Toda bounds, applies concavity of $\log \sinh x$, and uses the two exact telescopes. The zero-contraction case is handled before taking logarithms. This result is credited to the parallel formalization/research session. The proof and the distinction between checked finite components and written Jensen assembly are retained in its source.

Choose $n \geq \max(q, k)$ and $r = n$. Equations (1) and (38) yield the actual canonical selection estimate

$$\boxed{\min_{n \leq N < 2n} \epsilon_{h,k,N} \leq C_h n \sinh \left(\frac{1}{2n} \log \frac{V_{n-1} V_n}{V_{2n-1} V_{2n}} \right)}. \quad (39)$$

The chosen index is a member of the existing canonical family. The source representative, Taylor unit, kernel, action and trace are not chosen again after selecting this index.

For the packet consisting exactly of the quartet in (2), $q_k \geq k$ and $L_{h,k}/q_k \geq \delta k/2$. The earlier exterior bound holds at every admitted index, including the one selected by (39). Since $\sinh$ is increasing on $[0, \infty)$, (4) follows. Moreover $\operatorname{arsinh}(ak) = \log k + O_a(1)$ for every fixed $a > 0$, which proves the stated threshold 2.

A proved upper bound with $\limsup \mathcal{B}_{h,k}/(q_k \log k) < 2$ would contradict (4). Such an upper bound is **not** an output of this note. The previous sufficient target $\mathcal{B}_{h,k} = o(q_k \log k)$ remains sufficient, but (4) specifies the larger quantitative threshold against which a future upper estimate can be compared. No repeated cost-free exterior operation is used: the multiplicity correction in the new formalization is retained.

S20.8 8. The remaining four volumes retain their finite jet maps

The previous source/relation determinant identity remains

$$V_N = \frac{\mathfrak{D}_{N+1}}{\mathfrak{B}_{N-q+1}}. \quad (40)$$

In the parallel full-jet transfer coordinates (PR #24), let $a = N - q + 1$, let F_a be its $2q$ by $2q$ raw confluent-jet matrix, and let V be its raw-derivative Vandermonde matrix, with every factorial retained. Its established identity is

$$V_N = \left(\prod_{j=a}^{a+q-1} \omega_{h,k,j} \right) \frac{\det V}{\det F_a}. \quad (41)$$

For the window $n = r = q$, the four transfer indices are exactly $0, 1, q, q+1$. Put $\Omega_j = \prod_{i=j}^{j+q-1} \omega_{h,k,i}$. Then

$$\boxed{\exp \mathcal{B}_{h,k} = \frac{\Omega_0 \Omega_1}{\Omega_q \Omega_{q+1}} \frac{\det F_q \det F_{q+1}}{\det F_0 \det F_1}}. \quad (42)$$

The common Vandermonde cancels in this explicit ratio, not inside any underlying map. The transfer matrices and their inverses still need their actual arithmetic control; the fixed width alone gives no such bound.

The empty packet has $q = 0$, $V_N = 1$ as an empty determinant, and no positive-rank inverse or quartet estimate. The analytic inequalities (23)–(37) still apply to its theta seed, but are not statements about a nonexistent finite packet.

S20.9 9. The volume window is also two explicit retained-boundary costs

There is a second useful representation of the same remaining quantity, with no reference-density change. Fix $i < j$, both admissible. In the original monic polynomial basis put

$$F_{i,j} = [b_{i+1}, \dots, b_j], \quad \Omega_{i,j} = \text{diag}(\omega_{i+1}, \dots, \omega_j), \quad b_a = [p_a]_\chi. \quad (43)$$

The kernel update is the actual sum $K_j = K_i + F_{i,j}\Omega_{i,j}^{-1}F_{i,j}^*$, where $K_i = G_i^{-1}$. The matrix determinant lemma gives

$$\boxed{\frac{V_i}{V_j} = \det(I_{j-i} + \Omega_{i,j}^{-1}F_{i,j}^*G_iF_{i,j})}. \quad (44)$$

This determinant has positive real value. Its factors are $1 + \lambda_a$, where $\lambda_a \geq 0$ are the generalized eigenvalues of the Hermitian pair $(F_{i,j}^*G_iF_{i,j}, \Omega_{i,j})$. No non-Hermitian matrix is asserted positive in an unspecified Euclidean metric.

Let $T_{i,j}$ have columns $\mathcal{V}_{h,k}p_{i+1}, \dots, \mathcal{V}_{h,k}p_j$. The original boundary-layer isomorphism is

$$\mathbf{b}_{i,j} = T_{i,j} - R_iF_{i,j} : \mathbb{C}^{j-i} \xrightarrow{\sim} \mathcal{D}_j \cap \mathcal{D}_i^\perp, \quad \mathbf{b}_{i,j}^*\mathbf{b}_{i,j} = \Omega_{i,j} + F_{i,j}^*G_iF_{i,j}. \quad (45)$$

Its jets vanish; its highest polynomial coefficients give injectivity. Any new boundary can be reduced by these highest coefficients to an old boundary, and orthogonality then gives surjectivity. These statements prove the displayed map with the same original relation spaces, not only a dimension count. The representative update is

$$R_j = R_i + \mathbf{b}_{i,j}(\Omega_{i,j} + F_{i,j}^*G_iF_{i,j})^{-1}F_{i,j}^*G_i. \quad (46)$$

Every correction in (46) is an original theta boundary. Its split quotient image is e at the receiving fibre, and the input relation remains available in (45). Its cochain primitives are the same fixed-order divisions and tensor signs as in the previous cyclic source construction.

Apply (44) to $(i, j) = (q-1, 2q-1)$ and $(q, 2q)$. This proves

$$\boxed{\mathcal{B}_{h,k} = \sum_a \log(1 + \lambda_a^{(0)}) + \sum_a \log(1 + \lambda_a^{(1)})}. \quad (47)$$

In particular

$$\mathcal{B}_{h,k} \leq \text{Tr}(\Omega_{q-1,2q-1}^{-1}F^*G_{q-1}F) + \text{Tr}(\Omega_{q,2q}^{-1}F^*G_qF), \quad (48)$$

where each F has its own indicated source and target from (43). When this trace bound is too large, (47) retains the full logarithmic cost rather than replacing it by its linear upper bound. The analytic norm estimate in (1) does not bound (47); it supplies the other factor in (39).

S20.10 10. Deligne reading and what has actually been transferred

The six supplied S20 parts were reassembled in this turn. Their individual chunk hashes matched, and the assembled archive has 216,580,466 bytes and SHA-256 e2005bf31e1fc362765f73c315c855e0f504f24f34d3a0ab188049da522b7c8. This verifies the supplied bytes, not every transcription claim in them.

I read the TeX for Definition 1.3.5, Lemmas 3.2.10–3.2.12, the tensor argument 3.2.13, and Corollary 3.3.6 in the nested source files. I compared those exact passages with the supplied top-level French/English frozen page records at printed pages 158, 203, and 206. No PDF text extraction or OCR was used. The source review

records a genuine inherited transcription fault: old `fr_seg2.tex` writes a weight bound ≤ 2 at 3.2.10, whereas the controlling page record says < 2 ; only the latter, with integrality, implies ≤ 1 . The old file also corrupts the explicit squared-eigenvalue step in 3.2.13. Those old files remain unmodified; they are not used as authority for these comparisons. No claim of a full independent audit of Weil II is made.

Deligne’s determinant/rank operation and the upper/dual-lower architecture remain attached to the programme’s specified exterior and residue maps. Here the additional estimate is a characteristic-zero analytic estimate for the actual source, (1), followed by the endpoint selection (39). This is not a statement that the new base satisfies Deligne’s finite-field hypotheses. The remaining volume estimate has not been inferred from purity, positivity of a Gram, or the mere existence of the support.

The new result is therefore a completed analytic component of the current route: its two endpoint monic norms have the required $O_h(q_k)$ scale on the actual quartet window. The other session’s four-volume theorem now leaves the explicitly specified relation-volume cost as the remaining quantitative input on that window.

S20.11 11. Proof and computation status

Sections 3–7 contain the new written analytic argument. Sections 8–9 contain explicit finite comparisons and a handoff for checking them using the existing quotient and matrix library. The standard complex-analysis, gamma and Legendre facts used in the argument are proved to the extent needed or referenced below. No general novelty claim is made for these classical ingredients.

The accompanying checker tests finite exact identities: coordinate factors, Legendre extremal norms, the local algebra in the interval argument, convolution moments on declared Laplace models, source quotients, block updates, raw confluent-jet endpoint factors, the volume telescope, and retained support cases. These tests do not certify the analytic inequalities by sampling them. There is no new Lean certificate and no interval-certified value of C_h .

This continuation makes no remote changes. The integration files are add-only, and the parallel formalization branches and the reader’s existing sources are left untouched.

The attached four-endpoint criterion can be sharpened using its own exact radius identity. The improvement comes from multiplying the consecutive-step identities *before* discarding their imbalance terms. This preserves the fact that each interior volume contraction occurs in two adjacent control estimates.

The resulting four-endpoint bound is never weaker than the attachment's bound. It also has a simpler corollary:

$$\min_{0 \leq j < r} \epsilon_{h,k,n+j} \leq \left(\frac{\omega_{n+r} V_n}{\omega_n V_{n+r}} \right)^{1/(2r)}. \quad (1)$$

This corollary uses only two quotient volumes and two monic norms. It is useful for controlling large contractions, although it need not outperform the original bound when the contractions are small.

These are deductions below from the supplied exact-radius, positivity, and monotonicity hypotheses—not an assertion that the remaining arithmetic endpoint estimates have been established. The attachment itself distinguishes that analytic obligation from the existing finite formalizations.

S21.0.1 1. An exact product identity for a whole degree window

Fix the original packet h , tensor degree k , and cyclic dimension $q \geq 1$. Work at the original observation $\theta = 0$, or at a fixed admissible tilt for which the supplied identities hold. Suppress h, k, θ from the notation.

Retain

$$V_N = \det G_N > 0, \quad \omega_N > 0, \quad \delta_N = \frac{V_N}{V_{N-1}} \in (0, 1],$$

and write

$$\phi_N = \sigma - \partial_\theta \log V_N$$

for the original phase. The source identity is

$$\epsilon_N^2 + \phi_N^2 = \frac{\omega_{N+1}}{\omega_N} (1 - \delta_N) (\delta_{N+1}^{-1} - 1), \quad N \geq q. \quad (2)$$

The phase is therefore retained on the left, not set to zero.

Take a consecutive window

$$N = n, \dots, n + r - 1, \quad n \geq q, \quad r \geq 1,$$

and define

$$d_j = \delta_{n+j} \quad (0 \leq j \leq r), \quad \Omega_{n,r} = \frac{\omega_{n+r}}{\omega_n}.$$

Multiplication of (2) gives

$$\begin{aligned} \prod_{j=0}^{r-1} (\epsilon_{n+j}^2 + \phi_{n+j}^2) &= \Omega_{n,r} \prod_{j=0}^{r-1} \frac{(1 - d_j)(1 - d_{j+1})}{d_{j+1}} \\ &= \Omega_{n,r} \frac{(1 - d_0)(1 - d_r)}{\prod_{j=1}^r d_j} \prod_{j=1}^{r-1} (1 - d_j)^2. \end{aligned}$$

Since

$$\prod_{j=1}^r d_j = \frac{V_{n+r}}{V_n},$$

the exact window formula is

$$\prod_{j=0}^{r-1} (\epsilon_{n+j}^2 + \phi_{n+j}^2) = \frac{\omega_{n+r} V_n}{\omega_n V_{n+r}} (1 - d_0)(1 - d_r) \prod_{j=1}^{r-1} (1 - d_j)^2. \quad (3)$$

The squared interior factors are essential: each interior contraction belongs to two consecutive radius identities. The first and last contractions occur only once.

Put

$$E_{n,r} = \min_{0 \leq j < r} \epsilon_{n+j}.$$

Then

$$E_{n,r}^{2r} \leq \prod_{j=0}^{r-1} \epsilon_{n+j}^2 \leq \prod_{j=0}^{r-1} (\epsilon_{n+j}^2 + \phi_{n+j}^2).$$

All factors $1 - d_j$ lie in $[0, 1)$. Dropping them from the right of (3) proves (1).

This proof does not require a supremum over recurrence coefficients, an estimate for every intermediate inverse matrix, or a choice of a different Gram.

S21.0.2 2. The sharper bound from the same four endpoint volumes

For $r \geq 2$, define the three endpoint ratios

$$\alpha = \frac{V_n}{V_{n-1}}, \quad \beta = \frac{V_{n+r}}{V_{n+r-1}}, \quad t = \frac{V_{n+r-1}}{V_n}.$$

Thus

$$d_0 = \alpha, \quad d_r = \beta, \quad \prod_{j=1}^{r-1} d_j = t,$$

with $0 < \alpha, \beta, t \leq 1$. Also retain the attachment's norm factor

$$\mathcal{A}_{n,r} = \left(\frac{\omega_{n+r}}{\omega_n} \right)^{1/(2r)}.$$

The sharpened theorem is

$$E_{n,r} \leq \mathcal{U}_{n,r}, \quad (4)$$

where

$$\mathcal{U}_{n,r} = \mathcal{A}_{n,r} \left(\frac{(1-\alpha)(1-\beta)}{\beta t} \right)^{1/(2r)} \left(1 - t^{1/(r-1)} \right)^{(r-1)/r}. \quad (5)$$

Only

$$V_{n-1}, \quad V_n, \quad V_{n+r-1}, \quad V_{n+r}, \quad \omega_n, \quad \omega_{n+r}$$

are needed—the same endpoint data used in the attachment. Its existing criterion combines the four volumes into one logarithmic budget; (5) retains their separate contributions.

Proof Let $s = r - 1$. For positive contractions $d_1, \dots, d_s \leq 1$ with product t ,

$$\prod_{j=1}^s (1 - d_j) \leq (1 - t^{1/s})^s. \quad (6)$$

If a $d_j = 1$, the left side is zero, so the inequality is immediate. Otherwise set $v_j = -\log d_j > 0$. The function

$$f(v) = \log(1 - e^{-v})$$

has

$$f''(v) = -\frac{e^{-v}}{(1 - e^{-v})^2} < 0.$$

Jensen's inequality gives

$$\sum_{j=1}^s \log(1 - e^{-v_j}) \leq s \log \left(1 - e^{-(v_1 + \dots + v_s)/s} \right).$$

Exponentiating and using $e^{-\sum v_j} = t$ proves (6). This is an application of the ordinary concavity form of Jensen's inequality, not a new general inequality (National Institute of Standards and Technology [NIST], n.d.-b, §1.7(iv)). (DLMF)

Insert (6) into (3):

$$\prod_{j=0}^{r-1} (\epsilon_{n+j}^2 + \phi_{n+j}^2) \leq \Omega_{n,r} \frac{(1 - \alpha)(1 - \beta)}{\beta t} (1 - t^{1/s})^{2s}.$$

Taking the nonnegative $2r$ -th root proves (4)–(5). $\square$

For $r = 1$, there is no interior product and no fractional exponent involving $r - 1$. The separate formula is simply

$$\epsilon_n \leq \sqrt{\frac{\omega_{n+1}}{\omega_n}} \sqrt{(1 - \alpha)(\beta^{-1} - 1)}. \quad (7)$$

It retains the exact contraction contribution at that single step.

Comparison with the attached criterion The attachment proves

$$E_{n,r} \leq \mathcal{A}_{n,r} \sinh \left(\frac{\mathcal{B}_{n,r}}{2r} \right), \quad \mathcal{B}_{n,r} = \log \frac{V_{n-1} V_n}{V_{n+r-1} V_{n+r}}.$$

Its proof first replaces each exact contraction product by a hyperbolic-sine square and then applies Jensen. The new endpoint expression satisfies

$$\mathcal{U}_{n,r} \leq \mathcal{A}_{n,r} \sinh \left(\frac{\mathcal{B}_{n,r}}{2r} \right). \quad (8)$$

To see this, fix the four endpoints. Equation (6) shows that the product of the exact local contraction terms is maximized when all interior ratios equal $t^{1/(r-1)}$. Apply the attachment's local upper inequality and its Jensen inequality to that maximizing scalar sequence. Their endpoint budget is still exactly $\mathcal{B}_{n,r}$, so their upper bound dominates the maximum used in (5). Degenerate cases follow directly or by continuity.

A useful explicit comparison occurs for geometric volume contraction:

$$V_{n+j} = V_{n-1} d^{j+1}, \quad d = e^{-v} \in (0, 1).$$

Then

$$\alpha = \beta = d, \quad t = d^{r-1},$$

and (5) becomes

$$\mathcal{U}_{n,r} = \mathcal{A}_{n,r} \frac{1-d}{\sqrt{d}} = 2\mathcal{A}_{n,r} \sinh(v/2). \quad (9)$$

The previous bound is $\mathcal{A}_{n,r} \sinh v$. Their ratio is

$$\frac{\text{previous bound}}{\mathcal{U}_{n,r}} = \cosh(v/2).$$

The improvement can therefore be substantial, rather than merely a rearrangement of the same estimate.

Exact scope of sharpness Equation (5) is sharp for the **relaxed scalar problem** consisting of positive norm sequences, nonincreasing positive volume sequences, and identity (2).

For strictly contracting endpoints, choose all interior $d_j = t^{1/(r-1)}$. Write

$$f_j = (1 - d_j)(d_{j+1}^{-1} - 1) > 0.$$

Set

$$\frac{\omega_{n+j+1}}{\omega_{n+j}} = \frac{\mathcal{U}_{n,r}^2}{f_j}, \quad \phi_{n+j} = 0, \quad \epsilon_{n+j} = \mathcal{U}_{n,r}.$$

The product of the specified norm ratios is exactly $\Omega_{n,r}$, so the prescribed norm endpoints are respected and equality holds.

This is **not** an assertion that every such extremizing scalar sequence arises from the arithmetic convolution measure. The additional moment, recurrence, and interpolation constraints of that measure remain relevant.

Neither the phase nor the interior imbalance needs to be forgotten With all interior contractions strictly below one, define the nonnegative concavity loss

$$\mathcal{J}_{n,r} = (r-1) \log(1 - t^{1/(r-1)}) - \sum_{j=1}^{r-1} \log(1 - d_j).$$

Equation (3) becomes the exact identity

$$\prod_{j=0}^{r-1} (\epsilon_{n+j}^2 + \phi_{n+j}^2) = \mathcal{U}_{n,r}^{2r} e^{-2\mathcal{J}_{n,r}}. \quad (10)$$

Thus the additional loss in passing to the endpoint bound is explicitly recorded.

For example, when the phases have been calculated, the sharper conclusion is

$$\prod_{j=0}^{r-1} (E_{n,r}^2 + \phi_{n+j}^2) \leq \mathcal{U}_{n,r}^{2r} e^{-2\mathcal{J}_{n,r}}. \quad (11)$$

The left side is an increasing polynomial in $E_{n,r}^2$. Its unique nonnegative threshold gives a phase-sensitive bound. No phase is presumed to vanish at a general auxiliary tilt.

S21.0.3 3. The simpler corollary reduces to a ratio of two determinant sequences

The quantity in (1) admits a cancellation that reduces the number of endpoint objects further. Define

$$\Lambda_N = \frac{\omega_N}{V_N}.$$

The supplied source formulas are

$$\omega_N = \frac{\mathfrak{D}_{N+1}}{\mathfrak{D}_N}, \quad V_N = \frac{\mathfrak{D}_{N+1}}{\mathfrak{B}_{N-q+1}}.$$

They use the original source and relation Gram determinants. The ordinary monic-norm and moment-determinant framework is also recorded in DLMF §18.2(iv), (ix); the arithmetic identification of the relation determinant is the supplied construction. (DLMF)

Consequently,

$$\Lambda_N = \frac{\mathfrak{B}_{N-q+1}}{\mathfrak{D}_N}. \quad (12)$$

The source determinant $\mathfrak{D}_{N+1}$ cancels literally. Equation (1) is therefore

$$E_{n,r} \leq \left(\frac{\Lambda_{n+r}}{\Lambda_n} \right)^{1/(2r)} = \left(\frac{\mathfrak{B}_{n+r-q+1} \mathfrak{D}_n}{\mathfrak{D}_{n+r} \mathfrak{B}_{n-q+1}} \right)^{1/(2r)}. \quad (13)$$

This uses two source determinants and two relation determinants. It does not identify the relation space with its quotient value.

The mass bookkeeping remains exact. Rescaling the fixed source measure by $c > 0$ would give

$$\omega_N \mapsto c\omega_N, \quad V_N \mapsto c^q V_N, \quad \Lambda_N \mapsto c^{1-q} \Lambda_N.$$

Hence Λ_{n+r}/Λ_n is unchanged. No rescaling is performed; this calculation explains the cancellation while retaining the original mass.

Connection to the confluent-transfer interface The attachment supplies

$$V_N = \left(\prod_{j=a}^N \omega_j \right) \frac{\det V}{\det F_a}, \quad a = N - q + 1,$$

with the full confluent-jet conventions retained.

It follows that

$$\Lambda_N = \frac{\det F_a}{\det V \prod_{j=a}^{N-1} \omega_j}.$$

For $a = n - q + 1$, equation (13) becomes

$$E_{n,r} \leq \left[\frac{\det F_{a+r}}{\det F_a} \prod_{j=0}^{q-2} \frac{\omega_{a+j}}{\omega_{a+r+j}} \right]^{1/(2r)}. \quad (14)$$

At $q = 1$, the product is empty and equals one.

Thus the simpler criterion requires **two transfer determinants**, rather than four, together with the displayed norm bands. The common confluent Vandermonde factor cancels through an explicit ratio. No modulus is inserted to conceal a phase: positivity of the total expression follows from its equality with $\Lambda_{n+r}/\Lambda_n > 0$.

A quantitative target with an explicit threshold The supplied exterior result gives

$$L_{h,k} \leq \epsilon_{h,k,N}$$

at every admitted degree. For the packet consisting exactly of the hypothetical quartet,

$$q_k = [1 + k(m-1)](k+1)^2, \quad L_{h,k} \geq \frac{\delta}{2} k q_k.$$

The exact-quartet qualification is necessary.

Therefore

$$\boxed{L_{h,k}^{2r} \leq \frac{\Lambda_{n+r}}{\Lambda_n}.} \quad (15)$$

A sufficient asymptotic estimate is now

$$\boxed{\frac{1}{2r(k)} \log \frac{\Lambda_{n(k)+r(k)}}{\Lambda_{n(k)}} - \log(k q_k) \rightarrow -\infty.} \quad (16)$$

For a more concrete sufficient condition, suppose

$$\mathcal{A}_{n,r} \leq C_h q_k$$

and, for some fixed $0 < \eta < 2$,

$$\frac{1}{r} \log \frac{V_n}{V_{n+r}} \leq (2 - \eta) \log k.$$

Then (1) gives

$$E_{n,r} \leq C_h q_k k^{1-\eta/2} = o(k q_k). \quad (17)$$

These are still estimates to prove for the actual arithmetic family. The deduction specifies their required scale; it does not derive them from determinant positivity.

S21.0.4 4. Independent calculation on a canonical polynomial fixture

I checked the product identities and the numerical improvement using a declared Gaussian fixture—not an actual zeta-zero packet.

Take the measure

$$d\mu(u) = \frac{7}{\sqrt{2\pi}} e^{-u^2/2} du,$$

of literal mass seven, and the quotient

$$C = \mathbb{C}[u]/(u^2 + 1).$$

Its monic orthogonal polynomials satisfy

$$Q_0 = 1, \quad Q_1 = u, \quad Q_{j+1} = uQ_j - jQ_{j-1},$$

with

$$\omega_j = 7j!.$$

In the quotient basis $(1, u)$, let $b_j = [Q_j]$, and construct

$$K_N = \sum_{j=0}^N \frac{b_j b_j^T}{\omega_j}, \quad G_N = K_N^{-1}.$$

These are constrained-minimum Grams calculated from the source, not assigned matrices. The resulting values include

$$G_2 = \text{diag} \left(\frac{7}{3}, 7 \right),$$

$$G_3 = \text{diag} \left(\frac{7}{3}, \frac{21}{11} \right), \quad G_4 = \text{diag} \left(\frac{42}{43}, \frac{21}{11} \right).$$

Retain the coordinate generator

$$A = \frac{1}{2}I + iT, \quad T = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}.$$

For $G = \text{diag}(g_0, g_1)$, direct calculation of

$$A^*G + GA - G = i(GT - T^T G)$$

gives

$$\epsilon^2 = \frac{(g_0 + g_1)^2}{g_0 g_1}.$$

Hence

$$(\epsilon_2^2, \epsilon_3^2, \epsilon_4^2) = \left(\frac{16}{3}, \frac{400}{99}, \frac{4225}{946} \right).$$

The five required volumes are

$$(V_1, V_2, V_3, V_4, V_5) = \left(49, \frac{49}{3}, \frac{49}{11}, \frac{882}{473}, \frac{980}{1333} \right).$$

For the window $n = 2, r = 3$,

$$\Omega_{2,3} = 60, \quad \alpha = \frac{1}{3}, \quad \beta = \frac{110}{279}, \quad t = \frac{54}{473}.$$

The comparison is

$$\begin{aligned} E_{2,3} &= 2.0100756305\dots, \\ (\epsilon_2 \epsilon_3 \epsilon_4)^{1/3} &= 2.1407199197\dots, \\ \mathcal{U}_{2,3} &= 2.1666731523\dots, \\ \text{attached endpoint bound} &= 2.5178436564\dots \end{aligned}$$

Thus

$$\boxed{2.0100756305 \leq 2.1407199197 \leq 2.1666731523 < 2.5178436564.} \quad (18)$$

A Wolfram kernel independently verified the rational Grams, all three exact radius identities, and symbolic versions of the window factorization for $r = 1, \dots, 8$. The general proof is the algebra above; these finite calculations are checks, not arithmetic interval certificates or additional Lean certificates.

S21.0.5 5. What remains attached to the selected degree

For the fixed arithmetic packet and window, let N_* be the first index attaining the finite minimum. Its representative remains the existing

$$R_{N_*} : C_{h,k} \longrightarrow \mathcal{B}^{\widehat{\otimes} k},$$

with

$$J^{(k)} R_{N_*} = \eta_{h,k}, \quad q^{(k)} R_{N_*} = \sigma_h^{\otimes k} \eta_{h,k}.$$

These are the supplied source and quotient maps. Selecting a degree does not alter their arithmetic unit, nilpotent jets, or cohomology classes.

At the corresponding support label, the lifted map is still

$$(\lambda_{N_*}, c) \longmapsto (\lambda_{N_*}, R_{N_*} c), \quad \tau \longmapsto \tau.$$

An original relation is sent by the quotient to the supported zero at that label. Its pre-quotient norm remains recorded by the relation determinant in (12)–(14).

There is also a computational qualification: **endpoint data certify the existence of a suitable degree; they do not generally identify which degree minimizes the allowance.** Locating N_* still requires evaluating candidate allowances or obtaining additional information about their distribution.

The completed continuation is the exact window product (3), its sharper four-endpoint consequence (5), and the reduced determinant/transfer criteria (13)–(14). No GitHub changes or new Lean verification were performed for these deductions. The remaining arithmetic task is now expressible as the specific growth estimate (16), with the full phase and interior-contraction loss available whenever the coarse endpoint observation is insufficient.

One of the analytic estimates in the new endpoint criterion is now proved for the actual arithmetic measure. For a fixed packet h , retaining all its selected zero orders, I obtain

$$\left(\frac{\omega_{h,k,2n}}{\omega_{h,k,n}} \right)^{1/(2n)} \leq C_h n, \quad n \geq k \geq 3,$$

where $C_h < \infty$ depends on h , but **not** on the tensor degree k or polynomial degree n .

This establishes the $O_h(q_k)$ polynomial-norm input proposed in the formalization session's handoff, on the explicit window $q_k \leq N < 2q_k$. That handoff had correctly left this arithmetic estimate unproved.

Combining the bound with its endpoint-selection theorem gives a sharper statement about the remaining source-relation volumes: **an off-line quartet would force**

$$\liminf_{k \rightarrow \infty} \frac{\log(V_{q_k-1} V_{q_k} / (V_{2q_k-1} V_{2q_k}))}{q_k \log k} \geq 2.$$

The upper bound excluding that volume growth is not proved here. The norm factor in this particular criterion, however, is no longer an assumed estimate.

Full derivation in the HTML reader · LaTeX · Formalization handoff · Complete package

S22.0.1 1. The estimate concerns the original arithmetic source

I read the current main revision, which now includes the exterior/trace formalization, and the endpoint and confluent-transfer developments in PRs #23 and #24. Their source maps remain the inputs here; I have not replaced them with another positive metric.

The base remains $\mathfrak{b}_\tau$, carrying

$$\begin{array}{ccc} G(\mathbb{Z}) & \xrightarrow{G(j)} & G(\mathbb{C}) \\ p\mathbb{Z} \downarrow & & \downarrow p\mathbb{C} \\ \mathbb{Z} & \xrightarrow{j} & \mathbb{C}. \end{array}$$

The target of $p\mathbb{Z}$ remains infinite. The maps preserve $e = 0^\bullet$ and external absence τ separately before the arithmetic observation.

Retain

$$C_+ = [V \xrightarrow{\Theta} \mathcal{B}], \quad Q = \mathcal{B}/\Theta V, \quad D = -x\partial_x, \quad g = 2\xi.$$

For the fixed packet,

$$h(s) = \prod_{\rho \in Z} (s - \rho)^{m_\rho}, \quad v_h = \frac{g}{h},$$

define the same density and convolution as before:

$$w_h(t) = \frac{|v_h(\frac{1}{2} + it)|^2}{2\pi}, \quad m_{h,k} = w_h^{*k}, \quad \int_{\mathbb{R}} m_{h,k} = \mu_h^k.$$

The source map is

$$\mathcal{V}_{h,k}P = P(D_1 + \cdots + D_k)(F_h^{\otimes k}), \quad \mathcal{M}F_h = v_h.$$

Its norm is exactly

$$\|\mathcal{V}_{h,k}P\|^2 = \int_{\mathbb{R}} |P(k/2 + iu)|^2 m_{h,k}(u) du.$$

The arithmetic observation still satisfies

$$J^{(k)}\mathcal{V}_{h,k} = \eta_{h,k}\pi_{\chi},$$

where

$$\eta_{h,k}[P] = v_h^{\otimes k}P(A_k)1, \quad v_h = j_h(g/h).$$

Thus the full arithmetic Taylor unit stays in the map.

The norm $\omega_{h,k,n}$ is the infimum over **monic degree- n polynomials in this source**. It belongs to the leading-coefficient quotient

$$\mathcal{P}_n/\mathcal{P}_{n-1}.$$

The arithmetic quotient is connected through the other exact sequence

$$0 \longrightarrow \mathcal{P}_{n-q} \xrightarrow{\times\chi} \mathcal{P}_n \xrightarrow{\pi_{\chi}} \mathbb{C}[S]/(\chi) \longrightarrow 0.$$

Multiplication by monic χ carries the leading-coefficient line at degree $n - q$ to the one at degree n . The arithmetic quotient sends that same relation to its supported zero. These maps connect the two norm calculations without identifying them. The original internal quotient retains labels and identifies precisely differences lying in the specified relation submodule.

S22.0.2 2. The new analytic input is a lower bound after three actual convolutions

The earlier gamma comparison supplied an upper envelope. For the endpoint norm ratio, I constructed a lower envelope for the **unchanged arithmetic density**.

The starting lemma is

$$\int_{T-1}^{T+1} |\zeta(\tfrac{1}{2} + it)|^2 dt \geq c_{\zeta}(1 + |T|)^{-42}, \quad T \in \mathbb{R},$$

for a fixed positive constant c_{ζ} . The exponent 42 is a sufficient explicit exponent; no optimal local mean-square estimate is claimed.

The local-mass proof For $|T| \geq 10$, put

$$f_T(z) = \zeta(\tfrac{1}{2} + iT + iz).$$

On the ellipse

$$z = \frac{1}{2}(w + w^{-1}), \quad |w| = 8,$$

the functional equation and the vertical-strip gamma estimate give

$$|f_T(z)| \leq M_T = C_0(1 + |T|)^6.$$

The relevant strip is fixed, and the zeta pole lies outside the ellipse. For the part with positive real component, the direct identity

$$\zeta(s) = \frac{s}{s-1} - s \int_1^\infty \{x\} x^{-s-1} dx$$

gives the needed polynomial growth; reflection handles the remaining part. These use the classical zeta functional equation and gamma estimates, without RH. (DLMF)

The absolutely convergent reciprocal Dirichlet series gives

$$|\zeta(2 + iT)| \geq \zeta(2)^{-1}.$$

Let

$$r_* = \frac{3 + \sqrt{13}}{2} < 4.$$

Then

$$\frac{1}{2} \left(-ir_* + \frac{1}{-ir_*} \right) = -\frac{3i}{2},$$

so f_T at this point is $\zeta(2 + iT)$.

Write

$$m_T = \max_{x \in [-1, 1]} |f_T(x)|.$$

The maximum principle on the annulus $1 \leq |w| \leq 8$, applied through the displayed coordinate map, gives

$$\zeta(2)^{-1} \leq m_T^\vartheta M_T^{1-\vartheta}, \quad \vartheta = 1 - \frac{\log r_*}{\log 8} > \frac{1}{3}.$$

Hence

$$m_T \geq \zeta(2)^{-3} M_T^{-2}.$$

Cauchy's estimate also gives

$$\sup_{[-1, 1]} |f'_T| \leq M_T.$$

Around a point attaining m_T , there is a one-sided interval of length $m_T/(2M_T)$ on which $|f_T| \geq m_T/2$. Therefore

$$\int_{T-1}^{T+1} |\zeta(\tfrac{1}{2} + it)|^2 dt \geq \frac{m_T^3}{8M_T} \geq \frac{\zeta(2)^{-9}}{8C_0^7} (1 + |T|)^{-42}.$$

On the remaining compact range of T , the integral is continuous and strictly positive. Its minimum supplies the remaining positive constant.

Carry the bound through g/h The original gamma factor and the elementary polynomial bound for h imply

$$w_h(t) \geq c_h^{(0)} e^{-\pi|t|/2} (1 + |t|)^{-2 \deg h} |\zeta(\tfrac{1}{2} + it)|^2.$$

This inequality is valid at selected centres through the entire identity $g = hv_h$; it does not divide by an unevaluated zero.

Consequently,

$$\int_{T-1}^{T+1} w_h(t) dt \geq c_h^{(1)} e^{-\pi|T|/2} (1 + |T|)^{-B_h}, \quad B_h = 42 + 2 \deg h.$$

Now w_h is continuous, integrable, and positive outside a discrete set. Thus $w_h * w_h$ is continuous and strictly positive everywhere. Define the actual compact quantities

$$b_h = \min_{|v| \leq 1} (w_h * w_h)(v) > 0, \quad \vartheta_h = \int_{-1}^1 w_h(v) dv > 0.$$

Restricting a nonnegative convolution integral gives

$$m_{h,3}(u) \geq b_h \int_{u-1}^{u+1} w_h(t) dt.$$

For the remaining $k - 3$ factors, restrict their integration variables to $[-1, 1]$. Their sum has absolute value at most $k - 3$. This proves

$$m_{h,k}(u) \geq c_h \vartheta_h^{k-3} e^{-\frac{\pi}{2}(|u|+k-3)} (1 + |u| + k - 3)^{-B_h}, \quad k \geq 3.$$

The original mass has not been changed. The complementary integration regions remain part of $m_{h,k}$; this is a lower bound obtained from one positive contribution to that same density.

S22.0.3 3. This proves the required endpoint norm bound

Fix $0 < b < \pi/2$, and retain the two original Laplace values

$$M_h(\pm b) = \int_{\mathbb{R}} e^{\pm bt} w_h(t) dt.$$

The exponential-series inequality and convolution identity give

$$\omega_{h,k,j} \leq (2j)! b^{-2j} (M_h(b)^k + M_h(-b)^k).$$

The trial polynomial is $(S - k/2)^j$, whose value on the original integration line is $i^j u^j$. The operator remains multiplication by S .

For the lower estimate, the exact least squared norm of a monic polynomial of degree n on $[-L, L]$ is

$$\mathfrak{l}_n(L) = \frac{2L^{2n+1}}{2n+1} \left(\frac{2^n (n!)^2}{(2n)!} \right)^2.$$

This follows from the leading coefficient and orthogonality of the Legendre polynomial. Under $S = k/2 + iu$, the retained leading phase is i^n , whose squared modulus is one. (DLMF)

Applying the lower convolution envelope on $[-L, L]$ yields

$$\omega_{h,k,n} \geq c_h \vartheta_h^{k-3} e^{-\frac{\pi}{2}(L+k-3)} (1 + L + k - 3)^{-B_h} \mathfrak{l}_n(L).$$

Set $L = n$, and apply the upper estimate at degree $2n$. The exact finite bound is

$$\left(\frac{\omega_{h,k,2n}}{\omega_{h,k,n}} \right)^{1/(2n)} \leq \left[\frac{(4n)! b^{-4n} (M_h(b)^k + M_h(-b)^k) e^{\frac{\pi}{2}(n+k-3)} (1 + n + k - 3)^{B_h}}{c_h \vartheta_h^{k-3} \mathfrak{l}_n(n)} \right]^{1/(2n)}.$$

For $n \geq k \geq 3$, this is at most $C_h n$.

The degree dependence follows directly from

$$\binom{2n}{n} \leq 4^n, \quad (4n)! \leq (4n)^{4n}, \quad n + k - 3 \leq 2n.$$

The factorial and monic-norm factors contribute $O(n)$ after taking the $2n$ -th root. The retained mass factors contribute bounded factors of the form $\exp(O_h(k/n))$. The polynomial lower-envelope factor contributes

$$(2n)^{B_h/(2n)},$$

which is uniformly bounded.

Equation (36) of the note gives a literal sufficient C_h , retaining all these constants. It is deliberately not optimized or presented as a numerically certified constant.

This establishes a bound on the actual arithmetic norm sequence, uniformly in the required tensor and polynomial degrees.

S22.0.4 4. The endpoint criterion now leaves a precise four-volume threshold

The formalization session's theorem is

$$\min_{0 \leq j < r} \epsilon_{h,k,n+j} \leq \left(\frac{\omega_{h,k,n+r}}{\omega_{h,k,n}} \right)^{1/(2r)} \sinh \left(\frac{1}{2r} \log \frac{V_{n-1} V_n}{V_{n+r-1} V_{n+r}} \right).$$

It selects a member of the existing canonical family. Its proof retains both telescopes and the zero-contraction case; the report distinguishes its checked finite components from the written Jensen assembly.

Taking $r = n \geq \max(q, k)$ now gives

$$\min_{n \leq N < 2n} \epsilon_{h,k,N} \leq C_h n \sinh \left(\frac{1}{2n} \log \frac{V_{n-1} V_n}{V_{2n-1} V_{2n}} \right).$$

For the packet **consisting exactly of** an off-line quartet

$$\frac{1}{2} \pm \delta \pm i\gamma, \quad \delta, \gamma > 0,$$

with common multiplicity m , retain

$$q_k = [1 + k(m-1)](k+1)^2$$

and the existing aggregate defect

$$L_{h,k} = 2\delta[1 + k(m-1)](k+1) \left\lfloor \frac{(k+1)^2}{4} \right\rfloor.$$

Here $q_k \geq k$, and

$$\frac{L_{h,k}}{q_k} \geq \frac{\delta k}{2}.$$

The exterior theorem bounds $L_{h,k}$ by every admitted allowance, including the degree selected above.

Define

$$\mathcal{B}_{h,k} = \log \frac{V_{q_k-1} V_{q_k}}{V_{2q_k-1} V_{2q_k}}.$$

Then

$$\frac{\delta k}{2} \leq C_h \sinh \left(\frac{\mathcal{B}_{h,k}}{2q_k} \right),$$

and therefore

$$\mathcal{B}_{h,k} \geq 2q_k \operatorname{arsinh} \left(\frac{\delta k}{2C_h} \right).$$

Since h is fixed,

$$\operatorname{arsinh}\left(\frac{\delta k}{2C_h}\right) = \log k + O_h(1).$$

This proves the threshold

$$\liminf_{k \rightarrow \infty} \frac{\mathcal{B}_{h,k}}{q_k \log k} \geq 2.$$

The remaining upper estimate in this endpoint criterion is therefore sharply specified. The previously proposed

$$\mathcal{B}_{h,k} = o_h(q_k \log k)$$

would suffice; an upper limit strictly below 2 would already contradict the displayed lower threshold. **Neither upper estimate is being claimed here.**

No second cost-free exterior iteration is used. The formalization session's correction to that iteration's multiplicity cost remains intact.

S22.0.5 5. Those four volumes are two explicit costs of retained e -relations

I also expressed the remaining volume quantity directly through the original relation layers.

For admitted degrees $i < j$, put

$$F_{i,j} = [b_{i+1}, \dots, b_j], \quad \Omega_{i,j} = \operatorname{diag}(\omega_{i+1}, \dots, \omega_j),$$

where $b_a = [p_a]_\chi$ retains all quotient coordinates.

The existing full-jet kernel has the exact update

$$K_j = K_i + F_{i,j} \Omega_{i,j}^{-1} F_{i,j}^*, \quad K_i = G_i^{-1}.$$

Thus

$$\frac{V_i}{V_j} = \det(I + \Omega_{i,j}^{-1} F_{i,j}^* G_i F_{i,j}).$$

The source map behind this determinant is

$$\mathfrak{b}_{i,j} = T_{i,j} - R_i F_{i,j} : \mathbb{C}^{j-i} \xrightarrow{\sim} \mathcal{D}_j \cap \mathcal{D}_i^\perp,$$

where $T_{i,j}$ has the actual source columns $\mathcal{V}_{h,kp_{i+1}}, \dots, \mathcal{V}_{h,kp_j}$.

Its jets vanish, its highest polynomial coefficients give the inverse onto the new relation layer, and its Gram is

$$\mathfrak{b}_{i,j}^* \mathfrak{b}_{i,j} = \Omega_{i,j} + F_{i,j}^* G_i F_{i,j}.$$

The representative update remains

$$R_j = R_i + \mathfrak{b}_{i,j} (\Omega_{i,j} + F_{i,j}^* G_i F_{i,j})^{-1} F_{i,j}^* G_i.$$

Every correction is an original theta boundary. The complete transport is

$$\mathbb{C}^{j-i} \xrightarrow{\mathfrak{b}_{i,j}} \mathcal{D}_j / \mathcal{D}_i \hookrightarrow \mathcal{B}^{\widehat{\otimes} k} / \mathcal{D}_i \longrightarrow \mathcal{B}^{\widehat{\otimes} k} / \mathcal{D}_j.$$

Its final composite is zero. In the original split lift, it is the receiving fibre's **supported zero**, not τ .

Applying this to

$$(i, j) = (q_k - 1, 2q_k - 1), \quad (i, j) = (q_k, 2q_k)$$

gives

$$\mathcal{B}_{h,k} = \sum_a \log(1 + \lambda_a^{(0)}) + \sum_a \log(1 + \lambda_a^{(1)}),$$

where each $\lambda_a^{(\ell)} \geq 0$ is a generalized eigenvalue of the corresponding explicit pair

$$(F_{i,j}^* G_i F_{i,j}, \Omega_{i,j}).$$

This is the remaining volume cost in terms of the relations that become e -zero. Their source norms and cross-pairings are still present before that quotient.

The PR #24 transfer coordinates provide another exact calculation of the same four endpoints. Only its matrices at indices

$$0, \quad 1, \quad q_k, \quad q_k + 1$$

are needed, together with the specified products of ω_j . The common confluent Vandermonde cancels only in the displayed endpoint ratio; its raw-derivative factorials remain in the underlying maps. The note spells out that formula.

S22.0.6 6. The Deligne reading is now tied to this estimate

I reassembled the six supplied S20 parts and verified their chunk hashes and the full archive hash. I then read the TeX passages for Definition 1.3.5, Lemmas 3.2.10–3.2.12, the tensor step 3.2.13, and Corollary 3.3.6, comparing them with the archive’s current page-local French and English records.

There is a genuine inherited transcription trap: the older French TeX gives ≤ 2 in Lemma 3.2.10, while the current page record gives < 2 . The subsequent use of integral weights requires the strict inequality to conclude ≤ 1 . The older TeX also corrupts the explicit squared-eigenvalue step in 3.2.13. Both discrepancies are recorded; the old files were not overwritten.

The relevant operation remains the one identified in the other session’s reading: **an additional estimate before tensor amplification improves the weight bound**. The determinant/exterior map itself does not supply that estimate.

This continuation supplies a characteristic-zero estimate for the actual source—the norm-window bound above—and composes it with the endpoint criterion. It does not import finite-field purity hypotheses onto $\mathfrak{b}_\tau$.

Source reading and discrepancy record

Verification and handoff The new checker passed **18 exact finite test methods** normally and under python -0, with identical successful records; deliberately failing controls failed in both modes. All **37 entries** of the preceding gamma package’s manifest verified, and its **17-method suite** passed fresh normal and optimized runs.

The analytic theorem has a written proof. These finite checks are not a Lean certificate, a numerical enclosure of C_h , or a proof of the remaining volume estimate.

The [add-only integration patch](#) adds fifteen files and passed local application and byte-for-byte checks. No remote branch was changed.

The completed advance is the required $O_h(q_k)$ norm estimate on the actual quartet window. The remaining endpoint-volume problem is now a concrete two-block cost of the original supported relations, with a proved off-line threshold of $2q_k \log k$.

S23 PR 23: complete original endpoint and multiplicity criterion

Source role. Original pinned PR23 source; later results have their own complete proofs.

Exact revision. 61dd03044ad56b2baf3671fa217497b0f4749c1259f841cdc8491846abbd2e46

Source SHA-256. 61dd03044ad56b2baf3671fa217497b0f4749c1259f841cdc8491846abbd2e46

S23.1 Sharper endpoint-only criterion and the scope of exterior iteration

This is a mathematical continuation of the supplied Toda and exterior notes. The general Jensen argument and exterior-multiplicity count below have written proofs; they are not additional Lean declarations. The norm-ratio product and overlapping-volume telescope are included in the finite formalization target list. No arithmetic asymptotic bound is claimed.

S23.1.1 1. Eliminate the supremum over recurrence coefficients

Retain a nonempty fixed packet and tensor degree k , cyclic dimension q , the actual positive monic norm sequence ω_N , the actual quotient volume $V_N = \det G_N$, and the source's exact control allowance ϵ_N . Choose consecutive admitted degrees $N = n, \dots, n+r-1$ with $n \geq q$ and integer $r \geq 1$. Put

$$B_{(n,r)} = \log(V_{(n-1)} V_n / (V_{(n+r-1)} V_{(n+r)})),$$

$$A_{(n,r)} = (\omega_{(n+r)} / \omega_n)^{1/(2r)}.$$

These are four endpoint quotient volumes and two endpoint polynomial norms of the existing family. Since V is positive and nonincreasing, $B_{(n,r)} \geq 0$. The source's finite upper bound implies

$$\min_{(0 \leq j < r)} \epsilon_{(n+j)} \leq A_{(n,r)} \sinh(B_{(n,r)}/(2r)). \quad (E1)$$

Unlike the preceding maximum-recurrence criterion, E1 needs no pointwise upper bound for every recurrence coefficient in the window.

Complete proof For $N = n+j$ set

$$x_j = (1/2) \log(V_{(N-1)} / V_{(N+1)}) \geq 0,$$

$$A_j = \sqrt{\omega_{(N+1)} / \omega_N} > 0.$$

The existing local estimate is $\epsilon_{(n+j)} \leq A_j \sinh(x_j)$. If any $x_j = 0$, the nonnegative allowance at that step is zero, and E1 follows. Otherwise all $x_j > 0$. The function $f(x) = \log(\sinh x)$ has

$$f''(x) = -1/\sinh(x)^2 < 0.$$

Finite Jensen therefore gives

$$\text{product}_j \sinh(x_j) \leq \sinh((\sum_j x_j)/r)^r.$$

Let E be the minimum of the nonnegative allowances. Multiplication of the local bounds gives

$$E^r \leq \text{product}_j \epsilon_{(n+j)} \leq (\text{product}_j A_j) \text{product}_j \sinh(x_j).$$

The actual products telescope:

$$\text{product}_j A_j = (\omega_{(n+r)} / \omega_n)^{1/2},$$

$$2 \sum_j x_j = \log(V_{(n-1)} V_n / (V_{(n+r-1)} V_{(n+r)})).$$

Taking the nonnegative r -th root proves E1. A finite minimum is attained, so E1 selects an actual original degree N inside the specified window. No favorable metric is selected independently, and its original theta representative, quotient and full jets remain attached.

The recurrence product is `VolumeWindow.norm_ratio_product`; the second telescope is `VolumeWindow.overlapping_log_telescope`, applied to $V(j)=V_{(n-1+j)}$. The Jensen and nonnegative-root assembly is this written proof rather than a claim about an unimplemented exterior/analytic declaration.

S23.1.2 2. Every input is an endpoint of the two original determinant sequences

The source's $\omega_j = D_{(j+1)}/D_j$ gives

$$A_{(n,r)} = [D_{(n+r+1)} D_{(n)} / (D_{(n+r)} D_{(n+1)})]^{1/(2r)}.$$

The four V -values in B are evaluated by $V_N = D_{(N+1)}/B_{(N-q+1)}$, with the source's literal relation determinant B . All indices are nonnegative because $n \geq q$. No negative-index determinant or inverse of a rank-deficient earlier kernel is used. The common mass factors cancel only in these displayed ratios; the source $\text{norm } \omega_0 = \mu_h^k$ has not been reset.

For the original quartet,

$$q_k = [1+k(m-1)](k+1)^2, \\ L_{(h,k)} \geq \delta k^* q_k / 2.$$

The exterior theorem gives $L_{(h,k)} \leq \epsilon_N$ at every admitted N . Thus E1 yields

$$L_{(h,k)} \leq A_{(n,r)} \sinh(B_{(n,r)}) / (2r). \quad (E2)$$

A proof that the right side is $o(k^* q_k)$ along admitted $n=n(k)$, $r=r(k)$ would exclude that fixed off-line quartet. One sufficient set of estimates is

$$r(k) \geq c_h q_k, \quad A_{(n,r)} = O_h(q_k), \\ B_{(n,r)} = o_h(q_k \log k),$$

for $c_h > 0$. Indeed $B/(2r) = o(\log k)$, so $\sinh(B/(2r)) \leq \exp(o(\log k)) = k^{o(1)}$, and the ratio to $k^* q_k$ tends to zero. These are candidate arithmetic estimates, not consequences of the formal telescope, positivity, the Toda equation, or Deligne's finite-field hypotheses.

The weighted endpoint criterion is sharp as an abstract sequence inequality: equality can occur when all x_j are equal and every $A_j \sinh(x_j)$ equals the same allowance. For arbitrary recurrence sequences it is strictly preferable to replacing $A_{(n,r)}$ by the largest A_j .

S23.1.3 3. A useful boundary on further exterior amplification

The supplied single exterior theorem is correct. It must not be reused with a rank-two hypothesis that no longer holds after exterior powering.

Suppose the original self-adjoint control H has spectrum

$$(+\epsilon, 0 \text{ repeated } q-2 \text{ times}, -\epsilon), \quad \epsilon > 0.$$

On the actual p -th exterior power, $1 \leq p \leq q$, the additive control has $+\epsilon$ and $-\epsilon$ each with multiplicity

$$r_p = \text{binomial}(q-2, p-1),$$

and zero with multiplicity $\text{binomial}(q-2, p) + \text{binomial}(q-2, p-2)$. This follows by the unscaled wedge basis: select the positive direction but not the negative, the negative but not the positive, or both/neither. In particular its operator norm is still ϵ , but its rank is $2r_p$, not generally two.

Apply an s -th exterior power to that whole space, whose dimension is $D_p = \text{binomial}(q, p)$. Its largest absolute additive-control eigenvalue is exactly

$$\epsilon \min(s, r_p, D_p - s), \quad 0 \leq s \leq D_p.$$

Proof: select positive eigenvectors first, zero eigenvectors next, and negative eigenvectors only when the degree forces them. There are r_p available positive directions and r_p negative ones. This attains the stated piecewise maximum; reversing the choices attains its negative. At $s=D_p$ the sum is zero. For example $q=4, p=2$ gives spectrum $(+\epsilon, +\epsilon, 0, 0, -\epsilon, -\epsilon)$, and the next exterior square has allowance 2ϵ .

This does not weaken the original determinant-line amplification or remove its nilpotent arithmetic action. It identifies the precise cost of iterating the operation on the entire exterior space, and prevents a spurious second cost-free amplification. The source's chosen determinant line has its own one-dimensional action and must remain distinguished from the complete first exterior power.

S23.1.4 4. Collaboration boundary

The formal work carries the exact source/quotient determinant and the two loss terms into the original-Gram trace certificate. The analytic collaborator can now estimate the two endpoint quantities in E1, or retain the exact phase and imbalance when the coarse upper bound is too large. The six-part Deligne archive and uploaded ZIP test suites were not opened in this execution environment; the source statements used here came from the complete pasted notes. The current GitHub correction and original source maps are unchanged.

S24 The complete original endpoint and Gamma join

Source role. Complete original EG.1-5 mathematical witness.

Source SHA-256. ce4af7908adc2f8003b6fe7e7f62068a1ee125c45412048159fde67f2cfb1b50

S24.1 Endpoint degree selection in the actual gamma-corrected coordinates

This short calculation joins the complete written endpoint criterion in PR #23 (reported source revision c720f40530eed2f5969dbabe94dfd3fddc0f507f) to the gamma convolution descent supplied on 13 September 2026. It uses the original arithmetic source, the original polynomial relation, and the same canonical quotient metric. It is a written substitution and finite-dependence proof, not an additional Lean theorem or a uniform arithmetic estimate.

S24.1.1 Objects and the estimate being evaluated

Fix the original packet h and tensor degree k . Put $\alpha_k = 2k$ and keep the source and reference Hankel determinants D_j and D_j^Γ of GD.28. Their positive quotient is $X_j = D_j/D_j^\Gamma$. For the original relation χ , of degree $q \geq 1$, let $Y_j = B_j/B_j^\Gamma$ and

$$T_N = \frac{X_{N+1}}{Y_{N-q+1}}, \quad V_N = \det G_N = V_N^\Gamma T_N, \quad N \geq q-1.$$

Here T_N is a positive scalar correction ratio, not the coordinate operator also denoted T in the Toda calculation. Let $n \geq q$ and $r \geq 1$ be integers. The endpoint criterion uses the actual quantities

$$\mathcal{A}_{n,r} = \left(\frac{\omega_{n+r}}{\omega_n} \right)^{1/(2r)}, \quad \mathcal{B}_{n,r} = \log \frac{V_{n-1} V_n}{V_{n+r-1} V_{n+r}}.$$

Its complete Jensen and telescoping proof gives

$$\min_{0 \leq j < r} \epsilon_{h,k,n+j} \leq \mathcal{A}_{n,r} \sinh \left(\frac{\mathcal{B}_{n,r}}{2r} \right). \quad (\text{EG.1})$$

No metric is selected here: the finite minimum is over the pre-existing canonical representatives at degrees n through $n+r-1$.

S24.1.2 Exact reference and arithmetic factors at the endpoints

At the original observation $\theta=0$, GD.28–29 gives

$$\omega_j = c_\lambda^k j! (\alpha_k)_j \frac{X_{j+1}}{X_j}. \quad (\text{EG.2})$$

Consequently,

$$\mathcal{A}_{n,r} = \left((n+1)_r (n+\alpha_k)_r \right)^{1/(2r)} \left(\frac{X_{n+r+1} X_n}{X_{n+r} X_{n+1}} \right)^{1/(2r)}. \quad (\text{EG.3})$$

The mass c_λ^k is retained in EG.2 and cancels between the two specified norms. The arithmetic mass μ_h^k was never assigned the value one. Each rising factorial in EG.3 is the exact r -factor product, not a large-degree approximation.

Substitution of $V_N = V_N^\Gamma T_N$ gives a second exact identity:

$$\mathcal{B}_{n,r} = \log \frac{V_{n-1}^\Gamma V_n^\Gamma}{V_{n+r-1}^\Gamma V_{n+r}^\Gamma} + \log \frac{T_{n-1} T_n}{T_{n+r-1} T_{n+r}}. \quad (\text{EG.4})$$

The reference quotient volumes in this expression are formed with the same χ , using its two conjugate differential factors in GD.30. The roots, their orders and the centre $k/2$ have not been changed. All ratios are positive, so the real logarithms and the indicated positive roots exist.

Equations EG.3–4, inserted in EG.1, express the endpoint selection estimate through an explicit reference factor, four source corrections X , and four source-to-relation corrections T . A pointwise upper bound $T_N \leq C_h(kq)$ does not control the denominator in EG.4. Neither of these exact identities supplies that missing quantitative estimate.

S24.1.3 Exact finite input count for the whole endpoint expression

The maximum source degree occurring in EG.1–4 is $n+r$: ω_{n+r} is its highest monic polynomial norm, and V_{n+r} is its highest quotient metric. Each defining source or relation Gram entry is the integral of a polynomial of degree at most $2(n+r)$ against the original arithmetic sum measure. The gamma coefficient theorem therefore proves that the complete endpoint expression is determined by

$$c_{h,0}, c_{h,1}, \dots, c_{h,2(n+r)}, \quad k, \lambda, \chi. \quad (\text{EG.5})$$

The zeroth coefficient carries the original total mass. The higher coefficients may have either sign. The finite coefficient-power formula and the Schur complement give the actual endpoint values; an arbitrary positive moment matrix cannot be inserted in their place. EG.5 gives a finite route for each chosen window. It does not bound the conditioning of the matrices or permit truncating the growing input count uniformly.

S24.1.4 Source roles

- [PR #23 endpoint proof at its supplied revision](#): finite Jensen selection, four-volume telescope, two-norm telescope. The user supplied its complete proof, which was read and the telescopes checked. Current CI/source review is recorded separately.
- Tau Gamma Convolution Descent, GD.25 and GD.28–35: exact coefficient transform and source/reference determinant ratios. The full original note and independent finite/analytic review are retained in this edition.
- GJ.1–8 in the gamma chapter: the explicit analytic map from the same one-factor moment function to the coefficient series, and finite source/quotient derivative jets.

The new content here is their literal endpoint-coordinate substitution and the maximum-degree input count. No additional theorem about zeta-zero locations or a completed growing-window bound is claimed.

S25 PR 24: complete original confluent transfer proof

Source role. Original historical PR24 proof, retained separately from the correction.

S25.1 Confluent transfer for the original source-relation volume

S25.1.1 Scope and current-main integration

This add-only analytic continuation starts from main fa4be32f87a9a90f3c02a07f7790dea95a1e7b0f, after the merge of PR #21 and its workflow-trigger correction. The PR #22 mathematical note was read at 811210d24b80813a08972ca23f919db015383137; its strict verification was in progress at that reading. This contribution neither modifies that branch nor treats pending checks as a certificate.

The source is the delivered Toda-volume continuation, following the cyclic and exterior-trace notes. Its full LaTeX was read directly. The new result is a fixed-width, full-jet transfer for the SAME canonical source/relation quotient metric. It applies the classical Christoffel transformation; it is not a claim to a new general orthogonal-polynomial theorem or to RH.

Keep $G(\mathbb{Z}) \rightarrow \mathbb{Z}$, with its infinite target, and its coefficient square to $G(\mathbb{C}) \rightarrow \mathbb{C}$. The structural base remains b_{τ} . Every supported coefficient map below retains $e=0^{\bullet}$ and external τ separately. The original theta complex is $C_{+}=[V \rightarrow \Theta \rightarrow B]$, with $D=-x \, d/dx$, $Q=B/\Theta \, V$ and $g=2 \, \xi$. No scalar, source function or measure is assigned a new normalization.

For a nonempty finite packet h of actual zeros with full orders, retain F_h with Mellin transform g/h . At tensor degree k , keep the actual cyclic sum module

$$\begin{aligned} C &= C[S]/(\chi), \quad q = \deg \chi \geq 1, \quad c = k/2, \quad A = M_S, \\ \eta[P] &= \epsilonpsilon_h^{(\text{tensor } k)} P(\sum_i M(s_i))1, \\ \epsilonpsilon_h &= j_h(g/h), \\ \text{Vcal } P &= P(D_1 + \dots + D_k)(F_h^{(\text{tensor } k)}). \end{aligned}$$

The original equations are

$$\begin{aligned} J^{(k)} \text{Vcal} &= \eta \, \pi_{\chi}, \\ q^{(k)} \text{Vcal} &= \sigma_h^{(\text{tensor } k)} \eta \, \pi_{\chi}. \end{aligned}$$

Its norm is the actual integral against $m_k = w_h^{\{k\}}$, where

$$w_h(t) = |(g/h)(1/2 + i \, t)|^{2/(2 \, \pi)}, \quad \text{integral } m_k = \mu_h^k.$$

The auxiliary measure is $d\mu_{\theta}(u) = \exp(\theta u) m_k(u) du$, $|\theta| < \pi/2$. Its mass is $M_h(\theta)^k$. θ in this expression is the real tilt parameter, not the theta-summation map. The exponential-moment bound from the source makes all finite derivatives below valid. At tilt zero the metric is the original arithmetic metric.

For $h=1$ the finite arithmetic quotient is zero. Its determinant is the empty determinant 1; the analytic seed and its mass remain, and $G(0)$ still has e and τ . The positive-dimensional inverses below require $q \geq 1$.

S25.1.2 1. Exact coordinate and raw-jet maps

Use the ring isomorphism

$$\Psi: C[S] \rightarrow C[u], \quad P \mapsto P(c + i \, u), \quad u \mapsto (S - c)/i.$$

Thus $d_u \Psi(P) = i \, \Psi(P')$, and multiplication by S remains $c + i \, M_u$. Define the original norm polynomial

$$\Pi(u) = \text{conj}(\chi)(c - i \, u) \, \chi(c + i \, u).$$

Its leading coefficient is literally $(-i)^q i^q = 1$. It is real and nonnegative on $\mathbb{R}$. Reflection gives $\chi^\dagger = (-1)^q \chi$, hence

$\psi(u) = i^{(-q)} \chi(c + i u)$ is real and monic,
 $\Pi = \psi^2$, $\Psi(\chi) = i^q \psi$.

The factor i^q remains in the source multiplication map. For distinct roots λ_a of χ , of complete lengths ℓ_a , put

$\zeta_a = (\lambda_a - c)/i$, $r_a = 2 \ell_a$, $r = \sum r_a = 2q$.

Define raw, NOT factorial-divided, derivative coordinates

$J_2 f = (f^{(d)}(\zeta_a))_{(a, 0 \leq d < r_a)}$.

Their kernel is (Π) . Their product uses the full binomial rule. Multiplication by u has matrix

$(X_{\Pi} v)_{(a,d)} = \zeta_a v_{(a,d)} + d v_{(a,d-1)}$, $v_{(a,-1)} = 0$.

All nilpotent orders and the coefficient d are retained.

Let Q_j be the real monic orthogonal source polynomials for $d\mu_\theta$, obtained by subtracting lower-degree projections, and write

$\omega_j = \int Q_j^2 d\mu_\theta > 0$,
 $a_j = \omega_j / \omega_{(j-1)}$, $a_0 = 0$,
 $b_j = \int u Q_j^2 d\mu_\theta / \omega_j$.

The source recurrence is

$u Q_j = Q_{(j+1)} + b_j Q_j + a_j Q_{(j-1)}$, $Q_{(-1)} = 0$.

No Q_j is divided by its norm. Set

$v_j = J_2 Q_j$,
 $F_n = [v_n, \dots, v_{(n+r-1)}]$,
 $V = [J_2 1, \dots, J_2 u^{(r-1)}]$.

Both are r by r . The raw confluent determinant is

$\det V = (\prod_{a=0}^{r-1} (d=0)^{(r_a-1)} d!) \prod_{a < b} (\zeta_b - \zeta_a)^{(r_a r_b)}$.

The fixed row order is part of this formula. $F_0 = V$ times the actual unit-triangular polynomial coefficient matrix; only their determinants are equal.

S25.1.3 2. Invertibility and the original relation polynomial

Invertibility proof. Suppose F lies in $\text{span}(Q_n, \dots, Q_{(n+r-1)})$ and $J_2 F = 0$. Then $F = \Pi H$ with $\deg H < n$. Orthogonality gives

$0 = \langle H, F \rangle = \int \Pi |H|^2 d\mu_\theta$.

The integrand is nonnegative and its weight is positive almost everywhere except finitely many points. Thus $H=0$, then $F=0$. For $n=0$ the degree argument suffices. Hence every F_n is invertible. This does NOT estimate its inverse uniformly.

Solve

$d_n = F_n^{(-1)} v_{(n+r)}$, $\vartheta_n = -(d_n)_0$.

The polynomial

$$\text{Qhat}_n = (Q_{(n+r)} - \sum_{(j=0)}^{(r-1)} (d_n)_j Q_{(n+j)}) / \text{Pi}$$

exists by exact raw-jet divisibility and is monic of degree n . Pairing its numerator with every polynomial of degree below n proves that Qhat_n is precisely the monic orthogonal polynomial for the ORIGINAL relation weight Pi dmu_θ . Its norm is

$$\begin{aligned} \text{nu}_n &= \int \text{Qhat}_n^2 \text{Pi dmu}_\theta \\ &= -(d_n)_0 \omega_n = \omega_n \quad \text{vartheta}_n > 0. \end{aligned} \quad (1)$$

Indeed only the Q_n column pairs with the degree- n quotient; its coefficient is $-(d_n)_0$. This proves $\text{vartheta}_n > 0$ with arbitrary nonreal and repeated nodes.

Let $K_n = [e_1, \dots, e_{(r-1)}, d_n]$. Then

$$\begin{aligned} F_{(n+1)} &= F_n K_n, \\ \det K_n &= (-1)^{(r-1)} (d_n)_0 = \text{vartheta}_n. \end{aligned} \quad (2)$$

The sign uses the displayed even $r=2q$. On the same jet algebra,

$$\begin{aligned} T_n &= F_n^{(-1)} X_{\text{Pi}} F_n, \\ T_{(n+1)} &= K_n^{(-1)} T_n K_n, \\ d_n &= (T_n - b_{(n+r-1)} I) e_{(r-1)} - a_{(n+r-1)} e_{(r-2)}. \end{aligned} \quad (3)$$

Thus the full operator and its jets have an explicit discrete transport, rather than only a determinant observation.

S25.1.4 3. Fixed-width determinant and quotient-volume formulas

Let D_n be the n by n source Hankel determinant, and B_n the corresponding determinant for Pi dmu_θ . $D_0 = B_0 = 1$. Orthogonality gives

$$D_n = \text{product}_{(j < n)} \omega_j, \quad B_n = \text{product}_{(j < n)} \text{nu}_j.$$

Multiplying (1) and (2) proves the complete confluent Christoffel identity

$$B_n / D_n = \text{product}_{(j < n)} \text{vartheta}_j = \det F_n / \det V. \quad (4)$$

This is a proof from the source division and norm, not a distinct-root approximation. Raw derivative factors remain in $\det V$.

For $N \geq q-1$ set $n = N - q + 1$. The source sequence is still

$$0 \rightarrow P_{(N-q)} \xrightarrow{\chi} P_N \rightarrow C[S] / \chi \rightarrow 0.$$

Its canonical least-norm quotient Gram G_N satisfies the existing Schur identity $\det G_N = D_{(N+1)} / B_n$. Consequently

$$V_N = \det G_N = (\text{product}_{(j=n)}^{(n+q-1)} \omega_j) \det V / \det F_n. \quad (5)$$

The constant coefficient map $S = c + i u$ has determinant of modulus one on each remainder basis, so these are the original quotient determinants, with that coordinate map retained.

For $n \geq 1$,

$$\begin{aligned} \delta_N &= V_N / V_{(N-1)} = \omega_N / \text{nu}_{(n-1)} \\ &= \omega_N / (\omega_{(n-1)} \text{vartheta}_{(n-1)}), \end{aligned} \quad (6)$$

$$\begin{aligned} R_N &= V_{(N-1)} / V_{(N+1)} \\ &= \omega_{(n-1)} \omega_n \text{vartheta}_{(n-1)} \text{vartheta}_n \\ &\quad / (\omega_N \omega_{(N+1)}). \end{aligned} \quad (7)$$

The transfer width $2q$ does not grow with N . The source recurrence and high-degree polynomial evaluation are still required; no computational-complexity or conditioning claim is inferred from the width alone.

S25.1.5 4. One additional solve retains the full phase

Differentiating actual source orthogonality under $\exp(\theta u)$ gives

$$d_{\theta} Q_j = -a_j Q_{(j-1)}, \quad d_{\theta} \log \omega_j = b_j.$$

For the first identity, every coefficient below $j-1$ vanishes by differentiated orthogonality; pairing with $Q_{(j-1)}$ gives $-\omega_j$. Let L_n have entries $(L_n)(j-1,j) = -a(n+j)$ for $1 \leq j \leq r$, all other entries zero. Then

$$F_n' = F_n L_n - a_n v_{(n-1)} e_{\theta}^T. \quad (8)$$

At $n=0$ the last term is zero. Trace of L_n is zero. Hence

$$\begin{aligned} (\log \det F_n)' &= -a_n e_{\theta}^T F_n^{-1} v_{(n-1)}, \\ (\log V_N)' &= \sum_{(j=n)}^{(n+q-1)} b_j \\ &\quad + a_n e_{\theta}^T F_n^{-1} v_{(n-1)}. \end{aligned} \quad (9)$$

Retain $T = (A - cI)/i$ and $\sigma = \text{Tr } T$, which is real. The previous source cross term is exactly

$$(b_N * G_N b_{(N+1)}) / \omega_N = i(\sigma - (\log V_N)').$$

Here b_N in that formula denotes the remainder vector of the S -monic source polynomial, not the scalar recurrence b_j . The factor i and the distinction of types remain. The phase is $\phi_N = \sigma - (\log V_N)'$. At zero tilt for a full quartet, evenness gives $\phi_N = 0$; it is not set to zero at a general tilt.

S25.1.6 5. The positive gaps are norms of actual source vectors

Put

$$Z_j = \psi \hat{Q}_j - Q_{(j+q)} \text{ in } P_{(j+q-1)}.$$

The leading terms cancel. Source orthogonality therefore proves

$$\Delta_j := \|Z_j\|^2 = \nu_j - \omega_{(j+q)} \geq 0. \quad (10)$$

The first term $\psi \hat{Q}_j$ is, through the explicit unit $i^{(-q)}$, an original χ relation. Its quotient is its supported zero. The difference Z_j instead has class $-[Q_{(j+q)}]$ in the original quotient. Its norm is not assigned to an absent element.

The SAME canonical rank-two control is $W_N = A * G_N + G_N A - k G_N$. Combining its previously proved radius identity with (6) gives, for $n \geq 1$,

$$\epsilon_N^2 = \Delta_{(n-1)} \Delta_n / (\nu_{(n-1)} \omega_N) - \phi_N^2. \quad (11)$$

Thus every factor in the upper bound

$$\epsilon_N \leq \sqrt{\Delta_{(n-1)} \Delta_n / (\nu_{(n-1)} \omega_N)}$$

comes from a specified positive source norm. Both gaps are computed by the transfer:

$$\begin{aligned} \Delta_{(n-1)} &= \omega_{(n-1)} \vartheta_{(n-1)} - \omega_N, \\ \Delta_n &= \omega_n \vartheta_n - \omega_{(N+1)}. \end{aligned}$$

The previous two-step bound is now

$$\epsilon_N \leq \sqrt{\omega_{(N+1)} / \omega_N} \cdot (R_{N-1}) / (2 \sqrt{R_N}), \quad (12)$$

with R_N from (7). At the first degree $N = q-1$, use the separate expression

$$\epsilon_{(q-1)}^2 = (\nu_0 - \omega_q) / \omega_{(q-1)} - \phi_{(q-1)}^2.$$

No inverse at the previous rank-deficient degree is introduced.

S25.1.7 6. Keep the actual conormal quotient, not a repeated first ideal

The helper algebra for the norm computation is $C[u]/\Pi$, isomorphic through $S=c+iu$ to $C[S]/\chi_1^2$. The actual depth-two object is $C[S]/\chi_2$, defined using the literal pullback of the original I^2 . The merged conormal work gives $\chi_2 \mid \chi_1^2$. The actual maps are

$$C[S]/\chi_1^2 \twoheadrightarrow C[S]/\chi_2 \twoheadrightarrow C[S]/\chi_1. \quad (13)$$

Their kernels are respectively $(\chi_2)/(\chi_1^2)$ and $(\chi_1)/(\chi_2)$. In raw jets they truncate at the indicated full orders and intertwine multiplication by S . Differentiation into depth one also commutes, since $\chi_1 \mid \chi_2$. The coordinate relation $d_u \Psi = i \Psi d_S$ is retained.

For $h=(s-\rho)^2$ and tensor degree two, $X=S-2\rho$ gives

$$C[X]/X^6 \twoheadrightarrow C[X]/X^5 \twoheadrightarrow C[X]/X^3.$$

The first kernel is the class of X^5 . The retained depth-two class X^3 has derivative $3X^2$ at depth one. These maps use one original scalar support. Their split lifts send quotient-killed classes to e at the receiving label and fix external τ .

The full multiplier $U=\text{product}_i(g/h)(s_i)$ retains the checked equation $\delta(U)P=U \delta(P)+(\delta U)P$. The second term is not discarded or presumed cyclic. The 2q-jet norm calculation is not counted as construction of new actual spectral multiplicities.

S25.1.8 7. Residual-controlled numerical interface

For an actual F and a specified candidate inverse Y , suppose a justified bound gives $\|I-YF\|_\infty \leq \eta < 1$. For candidate $\hat{d}$ and residual $r=v-F \hat{d}$, the exact Neumann argument proves

$$\|\hat{d}-d\|_\infty \leq \|Y\|_\infty \|r\|_\infty / (1-\eta). \quad (14)$$

This bounds the first coordinates used in (1) and (9). Arithmetic application requires certified input enclosures for the moments, source polynomials and zeros. Floating-point output alone is not a certificate.

Positive enclosures of ω and ϑ bound (7). Since $(R-1)^2/(4R)$ is increasing for $R \geq 1$, (12) yields a valid upper enclosure of ϵ^2 . The full phase can improve it through (11). Finite positivity/invertibility is not substituted for a uniform estimate of these residuals or inverse norms.

S25.1.9 8. Exact calibration and analytic target

For a declared Gaussian measure of literal mass seven and variance one, $\psi=u^2+1$, $q=2, n=2, N=3$, the calculation gives

```
(omega_0,...,omega_4)=(7,7,14,42,168),
vartheta_1=22, vartheta_2=86/3,
Qhat_1=u, Qhat_2=u^2-11/3,
Delta_1=112, Delta_2=700/3,
G_3=diag(7/3,21/11), epsilon_3^2=400/99.
```

An independent quotient-Gram calculation with $A=(1/2)I+i M_u$ gives the same result. The nonreal u -roots are algebraic fixtures, not zeros of ξ ; the nonzero allowance explicitly tests that the method does not manufacture purity. Repeated nodes, complex quartets, asymmetric atomic tilt derivatives and mass changes are covered by the expanded checks.

For the actual quartet retain

$$q_k=[1+k(m-1)](k+1)^2, \\ L_{\text{h,k}}=2 \delta [1+k(m-1)](k+1) \lfloor (k+1)^2/4 \rfloor.$$

The source exterior/filtration result gives $L_{\text{h,k}} \leq \epsilon_{\text{h,k,N}}$, and $L_{\text{h,k}}/(k q_k) \geq \delta/2$. Thus $\epsilon_{\text{h,k,N}} = o(k q_k)$, with fixed h and admitted $N \geq q_k$, is sufficient for the intended contradiction. The new representation attaches that exact target to TWO consecutive source-to-relation transfer coefficients and ONE phase solve. It has NOT proved that asymptotic bound.

No new Lean execution or arithmetic interval certificate is claimed. All new mathematical claims have the written proofs above at the retained source inputs. The original arithmetic function, unit, action, theta relations, residue pairing and trace remain unchanged.

S25.1.10 References and checks

Classical background: C. Krattenthaler (2021), 'A determinant identity for moments of orthogonal polynomials that implies Uvarov's formula for the orthogonal polynomials of rationally related densities', arXiv:2103.03969; NIST DLMF Section 18.2. The proofs above supply the particular confluent and arithmetic interfaces rather than attributing them wholesale to those references.

The expanded conversation delivery includes the complete LaTeX/HTML reader and twenty exact finite regression methods; both normal and optimized runs passed with matching records, and both deliberate-failure controls failed. The preceding Toda archive's 35 manifest entries verified and its 24-method checker passed fresh normal and optimized runs. These are stated verification scopes, not new Lean certificates. The public core checker in this directory independently tests the principal raw-jet, transfer, norm, determinant, volume and phase interfaces.

S26 Complete scalar volume comparison and arithmetic maps

Source role. Full VC.1-43 and VC.15a-b proof invoked by the AU continuation.

S26.1 An explicit scalar comparison for the original arithmetic quotient volumes

Date: 13 September 2026. This is the independent scalar comparison requested by the arithmetic volume upper-estimate lane. All inequalities below concern the original source and its original monic quotient. The displayed coordinate maps are invertible maps used in the proof; their Jacobians, phases, and the quotient units are retained.

S26.1.1 1. Original data and the finite answer

Let the fixed packet be a complete off-line quartet $1/2 \pm \delta \pm i\gamma$, with $\delta, \gamma > 0$ and common order $m \geq 1$. Put

$$c = k/2, \quad \ell = 1 + k(m-1), \quad q = \ell(k+1)^2, \quad R_0 = \sqrt{\delta^2 + \gamma^2}, \quad k \geq 3. \quad (\text{VC.1})$$

Keep the given monic annihilator $\chi \in \mathbb{C}[S]$ of degree q , with all its original local lengths. Its roots in the chart $S = c + iu$ have absolute value at most $\rho = kR_0$. The source is

$$w_h(t) = \frac{|(2\xi/h)(1/2 + it)|^2}{2\pi}, \quad m_k = w_h^*, \quad \mu_h = \int_{\mathbb{R}} w_h(t) dt, \quad M_h(a) = \int_{\mathbb{R}} e^{at} w_h(t) dt. \quad (\text{VC.2})$$

The proved arithmetic density estimate supplies its actual constants $c_h > 0$, $\vartheta_h > 0$, $B_h = 42 + 2 \deg h$, and $\alpha = \pi/2$:

$$m_k(u) \geq c_h \vartheta_h^{k-3} e^{-\alpha(|u|+k-3)} (1 + |u| + k - 3)^{-B_h}. \quad (\text{VC.3})$$

Choose any $0 < b < \alpha$. These are the established analytic inputs of the supplied Arithmetic Endpoint Bounds note, rather than added estimates on its unknown coefficients. Define the following literal finite numbers:

$$\begin{aligned} D &= \max\{1, 2/b, 2R_0\}, \quad T = Dq, \quad r = \rho/T, \quad N = 2q - 1, \\ \lambda_k(T) &= c_h \vartheta_h^{k-3} e^{-\alpha(T+k-3)} (1 + T + k - 3)^{-B_h}, \\ U_k(T) &= \mu_h^k + \frac{(2q-2)!}{(bT)^{2q-2}} (M_h(b)^k + M_h(-b)^k), \\ A_N &= \sqrt{\frac{2N+1}{2}} \frac{4^{N+1} - 1}{3}, \quad B_q(r) = \left(\frac{1+r}{1-r} \right)^q, \\ C_{k,q} &= \frac{U_k(T) A_{2q-1}^2 B_q(r)^2}{T \lambda_k(T)}. \end{aligned} \quad (\text{VC.4})$$

Here $q \geq k$, so $0 \leq r \leq 1/2$, and all denominators are strictly positive. The formula for U_k uses the usual $0! = 1$ convention, although the quartet has $q \geq 16$.

For every source degree $j \geq q - 1$, let H_j be the positive definite Gram matrix in the original ordered monomials $1, S, \dots, S^j$, let J_j be the coefficient matrix of remainder modulo the original χ , and set

$$K_j = J_j H_j^{-1} J_j^*, \quad G_j = K_j^{-1}, \quad V_j = \det G_j. \quad (\text{VC.5})$$

The finite Hermitian comparison is

$$K_q \preceq K_{2q-1} \preceq C_{k,q} K_q, \quad 0 \leq \log \frac{V_q}{V_{2q-1}} \leq q \log C_{k,q}. \quad (\text{VC.6})$$

The proof below establishes every algebraic and comparison step in (VC.6). In particular it proves $C_{k,q} \geq 1$, since the matrices in (VC.6) are positive definite.

S26.1.2 2. Exact source, quotient, and raw-jet maps

For each finite degree define the complex-linear isomorphism

$$\Psi_T : \mathbb{C}[S]_{\leq j} \longrightarrow \mathbb{C}[x]_{\leq j}, \quad (\Psi_T P)(x) = P(c + iTx). \quad (\text{VC.7})$$

Its inverse is $f \mapsto f((S - c)/(iT))$. A change of real variable gives the equality of the original norms

$$\int_{\mathbb{R}} |P(c + iu)|^2 m_k(u) du = \int_{\mathbb{R}} |(\Psi_T P)(x)|^2 T m_k(Tx) dx. \quad (\text{VC.8})$$

Thus the target measure in this equality has mass exactly μ_h^k . There is no mass divisor in the map. Define

$$\chi_T(x) = (iT)^{-q} \chi(c + iTx). \quad (\text{VC.9})$$

Its leading coefficient is one, its roots are the original u -chart roots divided by T , with the same multiplicities, and their absolute values are at most r . For every polynomial Q ,

$$\Psi_T(\chi Q) = (iT)^q \chi_T \Psi_T Q. \quad (\text{VC.10})$$

The nonzero scalar $(iT)^q$ is the exact unit connecting the two displayed generators. Consequently (VC.7) induces a quotient isomorphism

$$\bar{\Psi}_T : \mathbb{C}[S]/(\chi) \longrightarrow \mathbb{C}[x]/(\chi_T), \quad [P] \longmapsto [P(c + iTx)]. \quad (\text{VC.11})$$

Division is compatible with this map. Indeed, if $P = \chi Q + R$ with $\deg R < q$, then (VC.10) gives $\Psi_T P = (iT)^q \chi_T \Psi_T Q + \Psi_T R$, and $\deg \Psi_T R < q$; uniqueness of division proves

$$\text{rem}_{\chi_T} \Psi_T P = \Psi_T \text{rem}_{\chi} P. \quad (\text{VC.12})$$

If λ is a root in the original S chart and $z = (\lambda - c)/(iT)$, the raw derivative of order d obeys

$$(\Psi_T P)^{(d)}(z) = (iT)^d P^{(d)}(\lambda), \quad 0 \leq d < \text{ord}_{\lambda} \chi. \quad (\text{VC.13})$$

This follows by differentiating the affine composition d times. In local Taylor coordinates $P^{(d)}(\lambda)/d!$, the multiplier is still $(iT)^d$, while the factorial stays $d!$. The derivative phase has therefore been specified for every retained local length.

For precision at the matrix level, let $\mathbf{A}_j$ be the coefficient matrix of Ψ_T in increasing monomial degrees. Its columns are the coefficient vectors of $(c + iTx)^a$, $0 \leq a \leq j$; its diagonal is $(iT)^a$. Thus it is invertible and

$$\det \mathbf{A}_j = (iT)^{j(j+1)/2}. \quad (\text{VC.14})$$

Let tildes denote the target-coordinate Gram and remainder matrices. Equations (VC.8) and (VC.12) give

$$H_j = \mathbf{A}_j^* \tilde{H}_j \mathbf{A}_j, \quad \tilde{J}_j \mathbf{A}_j = \mathbf{A}_{q-1} J_j, \quad \tilde{K}_j = \mathbf{A}_{q-1} K_j \mathbf{A}_{q-1}^*. \quad (\text{VC.15})$$

The third equality follows by inserting the first two into $\tilde{J}_j \tilde{H}_j^{-1} \tilde{J}_j^*$. Hence $\tilde{G}_j = \mathbf{A}_{q-1}^{-*} G_j \mathbf{A}_{q-1}^{-1}$ and $\det \tilde{G}_j = T^{-q(q-1)} V_j$. The exact determinant factor is independent of j and cancels in the ratio in (VC.6). All subsequent norm estimates can therefore be pulled back to the original matrices by this proved congruence.

To state the same comparison in the original raw-jet coordinates, list the distinct roots of χ as λ_{ν} with full lengths d_{ν} , $\sum_{\nu} d_{\nu} = q$. In the fixed ordering of pairs (ν, a) , $0 \leq a < d_{\nu}$, define the square matrix

$$E_{(\nu,a),j} = \begin{cases} \frac{j!}{(j-a)!} \lambda_{\nu}^{j-a}, & j \geq a, \\ 0, & j < a, \end{cases} \quad 0 \leq j < q. \quad (\text{VC.15a})$$

Its action is the raw-derivative map on polynomials of degree below q . The exact Taylor formula shows that a polynomial has all these derivatives zero if and only if it is divisible by each $(S - \lambda_\nu)^{d_\nu}$, hence by their product χ . For degree below q , such a polynomial is zero. Thus E is injective, and equality of its domain and codomain dimensions proves that it is invertible. Every polynomial and its remainder differ by a multiple of χ , so their listed raw derivatives agree. Therefore the degree- j raw-jet matrix is exactly $F_j = EJ_j$, and

$$K_j^{\text{raw}} = F_j H_j^{-1} F_j^* = EK_j E^*, \quad G_j^{\text{raw}} = E^{-*} G_j E^{-1}, \quad \det G_j^{\text{raw}} = |\det E|^{-2} V_j. \quad (\text{VC.15b})$$

The multiplier $|\det E|^{-2}$ is independent of source degree. Consequently (VC.6) holds with the same constant in raw-jet coordinates and has the same determinant ratio. Equation (VC.13) gives the exact phase for each component when those raw jets are expressed in the affine chart. This is the direct typed relation between the remainder-kernel estimate and the raw-jet determinant calculation.

S26.1.3 3. The Legendre coefficient bound, proved in full

For a polynomial $f(x) = \sum a_j x^j$, write $\|f\|_{\text{coeff},1} = \sum |a_j|$. We prove

$$\|f\|_{\text{coeff},1} \leq A_N \|f\|_{L^2([-1,1],dx)}, \quad \deg f \leq N. \quad (\text{VC.16})$$

Define

$$L_j(x) = \frac{1}{2^j j!} \frac{d^j}{dx^j} (x^2 - 1)^j. \quad (\text{VC.17})$$

The leading coefficient is $\kappa_j = (2j)!/(2^j(j!)^2)$. Repeated integration by parts, with every boundary term zero because $(x^2 - 1)^j$ has zeros of order j at both endpoints, proves that L_j is orthogonal to every polynomial of degree below j . The same integration by parts gives

$$\int_{-1}^1 L_j(x)^2 dx = \frac{\kappa_j}{2^j} \int_{-1}^1 (1 - x^2)^j dx = \frac{2}{2j+1}. \quad (\text{VC.18})$$

Here the intermediate integral is $2^{2j+1}(j!)^2/(2j+1)!$. To verify that expression without any special-function identity, substitute $x = 2t - 1$, obtaining $2 \cdot 4^j \int_0^1 t^j (1-t)^j dt$. Repeated integration by parts proves $\int_0^1 t^a (1-t)^b dt = a!b!/(a+b+1)!$ for nonnegative integers a, b : integration by parts with antiderivative $t^{a+1}/(a+1)$ reduces b by one and increases a by one, and the case $b = 0$ is $1/(a+1)$. This proves (VC.18).

Leibniz's rule applied to $(x-1)^j(x+1)^j$ proves the exact finite formula

$$L_j(x) = 2^{-j} \sum_{a=0}^j \binom{j}{a}^2 (x-1)^{j-a} (x+1)^a. \quad (\text{VC.19})$$

The coefficient norm of a product is at most the product of its coefficient norms, by the triangle inequality for each convolution coefficient. The binomial theorem gives $\|(x \pm 1)^a\|_{\text{coeff},1} = 2^a$. Therefore

$$\|L_j\|_{\text{coeff},1} \leq \sum_{a=0}^j \binom{j}{a}^2 = \binom{2j}{j} \leq 4^j. \quad (\text{VC.20})$$

The middle equality is the coefficient of z^j in $(1+z)^j(1+z)^j$; the last inequality bounds one coefficient by the sum of all positive coefficients. The degrees and nonzero leading coefficients show that $L_0, \dots, L_N$ are a basis. Write $f = \sum_{j=0}^N a_j L_j$. By orthogonality and Cauchy-Schwarz,

$$|a_j| = \frac{2j+1}{2} \left| \int_{-1}^1 L_j(x) f(x) dx \right| \leq \sqrt{\frac{2j+1}{2}} \|f\|_{L^2([-1,1])}. \quad (\text{VC.21})$$

This formula is valid for complex coefficients because L_j is real. Combining (VC.20)–(VC.21), bounding $2j+1$ by $2N+1$, and summing the geometric series $\sum_{j=0}^N 4^j = (4^{N+1} - 1)/3$ proves (VC.16).

S26.1.4 4. The complete monic-division bound

Write the roots of χ_T , with repetitions, as $z_1, \dots, z_q$, where $|z_a| \leq r < 1$. Define the elementary symmetric polynomials e_a and complete homogeneous polynomials h_j by the finite coefficient identities

$$\prod_{a=1}^q (1 - z_a t) = \sum_{a=0}^q (-1)^a e_a t^a, \quad \prod_{a=1}^q (1 - z_a t)^{-1} = \sum_{j \geq 0} h_j t^j. \quad (\text{VC.22})$$

The second identity is a formal power-series identity: h_j is the sum of all monomials $z_1^{a_1} \cdots z_q^{a_q}$ with non-negative a_i and $\sum a_i = j$. There are $\binom{q+j-1}{j}$ such monomials: placing $q-1$ separators among $j+q-1$ positions gives a bijection with the exponent lists. Consequently

$$|e_a| \leq \binom{q}{a} r^a, \quad |h_j| \leq \binom{q+j-1}{j} r^j. \quad (\text{VC.23})$$

For $0 \leq s \leq q-1$, set $Q_s(x) = \sum_{j=0}^s h_j x^{s-j}$. Multiplying the two series in (VC.22) shows that every coefficient of degrees $q+s-1, q+s-2, \dots, q$ in $\chi_T Q_s$ is zero, while its coefficient of degree $q+s$ is one. It follows that

$$\text{rem}_{\chi_T} x^{q+s} = x^{q+s} - \chi_T Q_s, \quad \deg(x^{q+s} - \chi_T Q_s) < q. \quad (\text{VC.24})$$

The leading coefficient of $\chi_T Q_s$ is exactly one, so removing its leading term reduces its coefficient norm by exactly one. All remaining terms are the negative of the remainder. Thus

$$\begin{aligned} \|\text{rem}_{\chi_T} x^{q+s}\|_{\text{coeff},1} &= \|\chi_T Q_s\|_{\text{coeff},1} - 1 \\ &\leq (1+r)^q \sum_{j=0}^s \binom{q+j-1}{j} r^j - 1 \leq \left(\frac{1+r}{1-r}\right)^q. \end{aligned} \quad (\text{VC.25})$$

For the last inequality, the convergent geometric-series product at real $r < 1$ gives $\sum_{j \geq 0} \binom{q+j-1}{j} r^j = (1-r)^{-q}$. For $0 \leq j < q$, the remainder of x^j is x^j and its coefficient norm is one, also at most $B_q(r)$. Linearity and the triangle inequality now give the exact finite operator estimate

$$\|\text{rem}_{\chi_T} f\|_{\text{coeff},1} \leq B_q(r) \|f\|_{\text{coeff},1}, \quad \deg f \leq 2q-1. \quad (\text{VC.26})$$

Multiplicity was retained throughout the root list; no distinct-root interpolation or inverse Vandermonde estimate occurs here. If desired, the smaller literal finite constant

$$\max \left\{ 1, (1+r)^q \sum_{j=0}^{q-1} \binom{q+j-1}{j} r^j - 1 \right\} \quad (\text{VC.27})$$

can replace $B_q(r)$ in (VC.4), by the preceding proof.

S26.1.5 5. Original moment control and the remainder's source norm

For every nonnegative integer a and real u , the nonnegative Taylor terms of $e^{b|u|}$ imply

$$|u|^{2a} \leq (2a)! b^{-2a} e^{b|u|} \leq (2a)! b^{-2a} (e^{bu} + e^{-bu}). \quad (\text{VC.28})$$

Tonelli's theorem applied to the nonnegative product density and the identity $e^{b(t_1 + \dots + t_k)} = \prod e^{bt_i}$ gives

$$\int e^{\pm bu} m_k(u) du = M_h(\pm b)^k, \quad \int m_k(u) du = \mu_h^k. \quad (\text{VC.29})$$

Consequently the actual $2a$ -th moment is at most the right side of (VC.28) integrated using (VC.29). If v has degree at most $q-1$, each monomial has absolute value at most $\max\{1, |x|^{q-1}\}$. This gives

$$\begin{aligned} \int_{\mathbb{R}} |v(u/T)|^2 m_k(u) du &\leq \|v\|_{\text{coeff},1}^2 \int \max\{1, |u/T|^{2q-2}\} m_k(u) du \\ &\leq U_k(T) \|v\|_{\text{coeff},1}^2. \end{aligned} \quad (\text{VC.30})$$

The second inequality uses $\max\{1, t\} \leq 1 + t$ for $t \geq 0$, and the proved moment bound with $a = q - 1$. On the other hand, (VC.3) on $[-T, T]$ gives

$$\|P\|_{H_N}^2 \geq T \lambda_k(T) \|\Psi_T P\|_{L^2([-1,1])}^2. \quad (\text{VC.31})$$

Set $f = \Psi_T P$ and $v = \text{rem}_{\chi_T} f$. Equations (VC.8), (VC.12), (VC.16), (VC.26), (VC.30), and (VC.31), in that order, prove

$$\|\text{rem}_{\chi} P\|_{H_{q-1}}^2 \leq U_k(T) B_q(r)^2 A_N^2 \|\Psi_T P\|_{L^2([-1,1])}^2 \leq C_{k,q} \|P\|_{H_N}^2. \quad (\text{VC.32})$$

To specify the map's type, let $\iota_j : \mathbb{C}^{j+1} \rightarrow \mathcal{P}_j$ be $\iota_j(a) = \sum_{d=0}^j a_d S^d$, and let $\kappa : \mathbb{C}[S]/(\chi) \rightarrow \mathbb{C}^q$ send a class to the coefficient vector of its unique degree-below- q representative. Write $\mathcal{J}_j = J_j \iota_j^{-1} : \mathcal{P}_j \rightarrow \mathbb{C}^q$, and $s : \mathbb{C}^q \rightarrow \mathcal{P}_{q-1}$, $s(y) = \sum_{d=0}^{q-1} y_d S^d$. Then $\mathcal{J}_{q-1} s = I_{\mathbb{C}^q}$, and the original abstract quotient map π satisfies $\pi s = \kappa^{-1}$. The operator estimated in (VC.32) is exactly $s \mathcal{J}_N : \mathcal{P}_N \rightarrow \mathcal{P}_{q-1}$. Its restriction to $\mathcal{P}_{q-1}$ is the identity. In the formulas that follow, coefficient vectors and polynomials are identified only by the displayed ι_j .

S26.1.6 6. From the bounded remainder to the kernel inequality

The positive density in (VC.3) makes every polynomial Gram matrix positive definite. The remainder map J_j is surjective because its restriction to degrees below q is the identity. Thus K_j is positive definite. For completeness, define

$$R_j = H_j^{-1} J_j^* K_j^{-1}. \quad (\text{VC.33})$$

Then $J_j R_j = I$ by the definition of K_j . For $J_j z = 0$, $z^* H_j R_j = z^* J_j^* K_j^{-1} = 0$. Every lift of a quotient vector y is uniquely $R_j y + z$, $J_j z = 0$, so

$$\|R_j y + z\|_{H_j}^2 = y^* K_j^{-1} y + z^* H_j z. \quad (\text{VC.34})$$

The minimum lift norm is therefore exactly $y^* G_j y$. Degree inclusion enlarges the set of lifts and gives $G_{j+1} \preceq G_j$. Taking $P = R_N y$ in (VC.32), the degree- $(q-1)$ remainder is a lift of the same y , so

$$y^* G_q y \leq y^* G_{q-1} y \leq \|\text{rem}_{\chi} R_N y\|_{H_{q-1}}^2 \leq C_{k,q} y^* G_N y. \quad (\text{VC.35})$$

Together with $G_N \preceq G_q$, this gives $C_{k,q}^{-1} G_q \preceq G_N \preceq G_q$. Congruence by $G_q^{-1/2}$ bounds every eigenvalue of the middle matrix between $C_{k,q}^{-1}$ and one. Inversion reverses these positive eigenvalue inequalities; conjugating back proves the first inequality chain in (VC.6). Taking products of the same q eigenvalues proves its determinant statement. This proves the finite answer.

S26.1.7 7. The complete growth calculation and its exact gap

Let

$$X = \max\{1, M_h(b), M_h(-b)\}, \quad K = \max\{1, \vartheta_h^{-1}\}, \quad C_0 = \max\{1, 2/(3c_h D)\}. \quad (\text{VC.36})$$

These are bounding constants for the unchanged source. Since $bT \geq 2q$, $(2q-2)!/(bT)^{2q-2} \leq 1$. Also $M_h(b)^k + M_h(-b)^k = \int 2 \cosh(bu) m_k(u) du \geq 2\mu_h^k$. It follows that

$$U_k(T) \leq \frac{3}{2} (M_h(b)^k + M_h(-b)^k) \leq 3X^k. \quad (\text{VC.37})$$

The constants in (VC.4) further satisfy

$$A_{2q-1}^2 \leq \frac{2q}{9} 256^q, \quad \vartheta_h^{-(k-3)} \leq K^k. \quad (\text{VC.38})$$

On $[0, 1/2]$, the derivative of $\log((1+t)/(1-t))$ is $2/(1-t^2) \leq 8/3$. Integration from zero to r gives

$$\log B_q(r)^2 \leq \frac{16}{3} qr = \frac{16R_0}{3D} k. \quad (\text{VC.39})$$

Finally $1 + Dq + k - 3 \leq 1 + (D+1)q$, and $e^{-3\alpha} \leq 1$. Substituting (VC.37)–(VC.39) into the literal constant in (VC.4), and using $T = Dq$, yields

$$\begin{aligned} \log C_{k,q} &\leq (\alpha D + \log 256)q + \left(\log(XK) + \alpha + \frac{16R_0}{3D} \right) k \\ &\quad + B_h \log(1 + (D+1)q) + \log C_0. \end{aligned} \quad (\text{VC.40})$$

Thus an explicit upper bound on the requested original central volume is

$$\begin{aligned} 0 \leq \log \frac{V_q}{V_{2q-1}} &\leq (\alpha D + \log 256)q^2 \\ &\quad + \left(\log(XK) + \alpha + \frac{16R_0}{3D} \right) kq \\ &\quad + B_h q \log(1 + (D+1)q) + q \log C_0. \end{aligned} \quad (\text{VC.41})$$

All constants in (VC.41) depend only on the fixed packet and the chosen b ; no constant depends on k or q . Since $q = [1 + k(m-1)](k+1)^2$, one has $k/q \rightarrow 0$ and $(\log q)/q \rightarrow 0$. In particular

$$\limsup_{k \rightarrow \infty} \frac{1}{q_k^2} \log \frac{V_{q_k}}{V_{2q_k-1}} \leq \alpha D + \log 256. \quad (\text{VC.42})$$

The proved central-window lower estimate in the companion factor-four note is

$$\log \frac{V_q}{V_{2q-1}} \geq 2(q-1) \left(\log k + \log \frac{\delta}{2C_h^{\text{bal}}} \right). \quad (\text{VC.43})$$

The precise comparison between (VC.41) and (VC.43) is therefore an interval of admissible growth, not an RH contradiction. After division by $q \log k$, the leading term of the upper bound is $(\alpha D + \log 256)q / \log k$. This diverges like $(\alpha D + \log 256)k^2 / \log k$ when $m = 1$, and like $(\alpha D + \log 256)(m-1)k^3 / \log k$ when $m > 1$. The upper bound is larger than the lower scale by those explicit factors. This calculation locates exactly the loss in this scalar route: (VC.16) controls every coefficient of a degree- $(2q-1)$ polynomial, and (VC.31) replaces the full source by its least value on a length- $2Dq$ interval. The remainder step itself has only $O(k)$ logarithmic cost by (VC.39).

The sharper raw-jet matrix determinant comparison in the parent lane retains the directional dependence discarded by the scalar estimates (VC.16) and (VC.31). Equations (VC.7)–(VC.15) and (VC.33)–(VC.35) give the exact maps through which the present scalar estimate bounds that same original quotient. No claim about the sharper determinant's asymptotic size is made here.

S26.1.8 8. Provenance and verification boundary

The inherited analytic input is (VC.3) and the finiteness of $M_h(\pm b)$, proved in the complete supplied Tau_Arithmetic_Endpoint_Bounds/NOTE.tex. The central lower bound (VC.43) is proved in the owner's complete FOUR_VOLUME_THRESHOLD.md continuation. This note proves (VC.4)–(VC.42) directly from those established input theorems, with full finite calculations. It does not replace the arithmetic weight, discard the mass, erase a raw-jet phase, shorten a local length, postulate the desired upper estimate, or assert RH. Any finite symbolic test accompanying this note tests the algebraic maps and constants; the written argument proves the estimates for all the indicated degrees.

S27 Complete all-degree division and affine raw-jet estimates

Source role. Full RB.1-37 proof with all original derivative factors.

S27.1 Exact finite remainder bound and affine raw-jet transport

This note proves the finite coefficient estimate requested for the volume-comparator calculation. All roots are counted with their original multiplicities. The degree, affine unit, complex phase, domains, and codomains remain explicit throughout.

S27.1.1 1. Polynomial spaces and the remainder map

Let $q \geq 1$ be an integer and write

$$\chi_x(x) = \prod_{a=1}^q (x - \lambda_a), \quad |\lambda_a| \leq R, \quad R \geq 0. \quad (\text{RB.1})$$

Repeated entries of $(\lambda_1, \dots, \lambda_q)$ record root multiplicity. Set

$$\mathcal{P}_d(x) = \left\{ \sum_{j=0}^d u_j x^j : u_j \in \mathbb{C} \right\}, \quad \|P\|_{1,x} = \sum_{j=0}^d |u_j|. \quad (\text{RB.2})$$

The exact linear map in this note is

$$\mathcal{R}_{\chi_x} : \mathcal{P}_{2q-1}(x) \longrightarrow \mathcal{P}_{q-1}(x), \quad P = \chi_x Q + \mathcal{R}_{\chi_x} P, \quad Q \in \mathcal{P}_{q-1}(x). \quad (\text{RB.3})$$

Existence follows by subtracting the leading coefficient times the corresponding monomial multiple of the monic polynomial χ_x , decreasing the degree at each step until it is below q . For uniqueness, the difference of two decompositions satisfies $\chi_x(Q_1 - Q_2) = r_2 - r_1$, where the right side has degree below q . A nonzero left side has degree at least q , so both sides vanish. Applying this uniqueness to linear combinations proves linearity. In particular $\mathcal{R}_{\chi_x} x^j = x^j$ for $0 \leq j < q$.

S27.1.2 2. The complete homogeneous division formula

Let e_a be the elementary symmetric polynomial of degree a in the listed roots, with $e_0 = 1$, and define the complete homogeneous polynomials by

$$h_\ell(\lambda_1, \dots, \lambda_q) = \sum_{\substack{\alpha_1, \dots, \alpha_q \geq 0 \\ \alpha_1 + \dots + \alpha_q = \ell}} \lambda_1^{\alpha_1} \cdots \lambda_q^{\alpha_q}, \quad h_0 = 1. \quad (\text{RB.4})$$

As an identity of formal power series,

$$\left(\sum_{a=0}^q (-1)^a e_a t^a \right) \left(\sum_{\ell=0}^{\infty} h_\ell t^\ell \right) = \prod_{a=1}^q (1 - \lambda_a t) \prod_{a=1}^q \left(\sum_{b=0}^{\infty} (\lambda_a t)^b \right) = 1. \quad (\text{RB.5})$$

There is no convergence requirement: every coefficient uses only finitely many factors and terms. Thus, for every integer $s \geq 1$,

$$\sum_{a=0}^{\min(q,s)} (-1)^a e_a h_{s-a} = 0. \quad (\text{RB.6})$$

For $0 \leq m \leq q-1$, put

$$Q_m(x) = \sum_{\ell=0}^m h_\ell x^{m-\ell}. \quad (\text{RB.7})$$

The coefficient of x^{q+m} in $\chi_x Q_m$ is one. For $1 \leq s \leq m$, the coefficient of x^{q+m-s} is the left side of (RB.6), hence zero. Therefore

$$x^{q+m} - \chi_x(x) Q_m(x) \in \mathcal{P}_{q-1}(x).$$

The uniqueness in (RB.3) now gives the exact division identity

$$\boxed{\mathcal{R}_{\chi_x} x^{q+m} = x^{q+m} - \chi_x Q_m.} \quad (\text{RB.8})$$

For completeness its individual coefficients are

$$[x^r] \mathcal{R}_{\chi_x} x^{q+m} = - \sum_{\substack{0 \leq a \leq q, 0 \leq \ell \leq m \\ a+\ell=q+m-r}} (-1)^a e_a h_\ell, \quad 0 \leq r < q. \quad (\text{RB.9})$$

This expression remains valid for repeated and zero roots without taking limits.

S27.1.3 3. Explicit coefficient-norm bound

The coefficient norm is submultiplicative. Indeed, if $U = \sum u_j x^j$ and $V = \sum v_k x^k$, then

$$\|UV\|_{1,x} = \sum_r \left| \sum_{j+k=r} u_j v_k \right| \leq \sum_{j,k} |u_j| |v_k| = \|U\|_{1,x} \|V\|_{1,x}. \quad (\text{RB.10})$$

Consequently

$$\|\chi_x\|_{1,x} \leq \prod_{a=1}^q (1 + |\lambda_a|) \leq (1 + R)^q. \quad (\text{RB.11})$$

The number of weak compositions of ℓ into q nonnegative parts is $\binom{q+\ell-1}{\ell}$: place $q-1$ separators among a row of ℓ markers and those separators. Thus (RB.4) yields

$$|h_\ell| \leq \binom{q+\ell-1}{\ell} R^\ell, \quad \|Q_m\|_{1,x} \leq \sum_{\ell=0}^m \binom{q+\ell-1}{\ell} R^\ell. \quad (\text{RB.12})$$

In (RB.8), the leading monomial x^{q+m} and the remainder have disjoint degree supports. In particular

$$\|\chi_x Q_m\|_{1,x} = 1 + \|\mathcal{R}_{\chi_x} x^{q+m}\|_{1,x}. \quad (\text{RB.13})$$

Combining (RB.10)–(RB.13) proves, with the original radius retained,

$$\boxed{\|\mathcal{R}_{\chi_x} x^{q+m}\|_{1,x} \leq (1+R)^q \sum_{\ell=0}^m \binom{q+\ell-1}{\ell} R^\ell - 1, \quad 0 \leq m \leq q-1.} \quad (\text{RB.14})$$

When $R \leq 1$, the finite sum of binomial coefficients is

$$\sum_{\ell=0}^m \binom{q+\ell-1}{\ell} = \binom{q+m}{m}. \quad (\text{RB.15})$$

To verify this identity, its $m = 0$ case is $1 = 1$, and its induction step is Pascal's identity $\binom{q+m-1}{m-1} + \binom{q+m-1}{m} = \binom{q+m}{m}$. The right side of (RB.15) increases with m , as is also immediate from its sum expression. Define the exact integer

$$C_q = 2^q \binom{2q-1}{q-1} - 1. \quad (\text{RB.16})$$

Then $C_q \geq 1$, with $C_1 = 1$, and every column of the remainder map satisfies

$$\max_{0 \leq j \leq 2q-1} \|\mathcal{R}_{\chi_x} x^j\|_{1,x} \leq C_q. \quad (\text{RB.17})$$

The two central coefficients $\binom{2q-1}{q-1}$ and $\binom{2q-1}{q}$ are equal. Their sum is at most the sum of all coefficients of $(1+t)^{2q-1}$ at $t = 1$, which is 2^{2q-1} . Therefore

$$C_q \leq 2^{3q-2} - 1 < 8^q. \quad (\text{RB.18})$$

For an arbitrary $P = \sum_{j=0}^{2q-1} u_j x^j$, linearity and the triangle inequality give

$$\|\mathcal{R}_{\chi_x} P\|_{1,x} \leq C_q \|P\|_{1,x} < 8^q \|P\|_{1,x} \quad (P \neq 0). \quad (\text{RB.19})$$

The non-strict version with 8^q holds also for $P = 0$. In fact the induced operator norm between these coefficient ℓ^1 spaces equals the maximum column norm: the displayed triangle inequality proves the upper bound, and applying the operator to a monomial attaining the finite maximum proves the reverse inequality.

S27.1.4 4. Raw jets and the exact quotient section

Write the distinct roots as $\lambda_1^*, \dots, \lambda_s^*$, with multiplicities $m_1, \dots, m_s$, so $\sum_{\nu} m_{\nu} = q$. Define the raw-jet space and map by

$$\mathcal{J}_x = \bigoplus_{\nu=1}^s \mathbb{C}^{m_{\nu}}, \quad J_{\chi_x, d} : \mathcal{P}_d(x) \longrightarrow \mathcal{J}_x, \quad P \longmapsto \left(P^{(r)}(\lambda_{\nu}^*) \right)_{1 \leq \nu \leq s, 0 \leq r < m_{\nu}}. \quad (\text{RB.20})$$

The exact Taylor identity at a root is

$$P(x) = \sum_{r=0}^d \frac{P^{(r)}(\lambda_{\nu}^*)}{r!} (x - \lambda_{\nu}^*)^r.$$

It shows that the first m_{ν} raw derivatives vanish precisely when $(x - \lambda_{\nu}^*)^{m_{\nu}}$ divides P . Simultaneous divisibility by these distinct-root factors is equivalent to divisibility by their product χ_x : in the factorization of a nonzero polynomial over $\mathbb{C}$, the exponent at each distinct root must be at least the listed multiplicity. The zero polynomial is divisible by every factor. Hence, for $d \geq q$,

$$\ker J_{\chi_x, d} = \chi_x \mathcal{P}_{d-q}(x). \quad (\text{RB.21})$$

The restriction $J_{\chi_x, q-1}$ has zero kernel by degree, and both its domain and codomain have dimension q . It is therefore an isomorphism. Equation (RB.3) gives

$$J_{\chi_x, q-1} \mathcal{R}_{\chi_x} = J_{\chi_x, 2q-1}, \quad \mathcal{R}_{\chi_x} = J_{\chi_x, q-1}^{-1} J_{\chi_x, 2q-1}. \quad (\text{RB.22})$$

Thus this remainder map preserves every specified raw jet, including every derivative order required by multiplicity. Equivalently, the inclusion of $\mathcal{P}_{q-1}(x)$ followed by the quotient map is an isomorphism onto $\mathbb{C}[x]/(\chi_x)$, and (RB.3) is the unique representative of degree below q in that quotient class.

S27.1.5 5. Original S variable, affine unit, and phase

Let the original monic annihilator be

$$\chi(S) = \prod_{\nu=1}^s (S - \zeta_{\nu})^{m_{\nu}}, \quad c \in \mathbb{C}, \quad T > 0. \quad (\text{RB.23})$$

Use the requested transformed-polynomial notation with its full definition:

$$\bar{\chi}(x) = (iT)^{-q} \chi(c + iTx) = \prod_{\nu=1}^s \left(x - \frac{\zeta_\nu - c}{iT} \right)^{m_\nu}. \quad (\text{RB.24})$$

Here the bar symbol is defined by (RB.24); complex conjugation of a polynomial, if used elsewhere, has its separate coefficientwise definition. The displayed unit $(iT)^{-q}$ proves monicity and retains the full complex phase. The transformed root radius is exactly bounded by

$$\left| \frac{\zeta_\nu - c}{iT} \right| = \frac{|\zeta_\nu - c|}{T}; \quad \text{in particular } \max_\nu |\zeta_\nu - c| \leq T \implies R \leq 1. \quad (\text{RB.25})$$

For every $d \geq 0$, define the invertible linear map

$$\begin{aligned} A_{c,T,d} : \mathcal{P}_d(S) &\longrightarrow \mathcal{P}_d(x), & (A_{c,T,d}P)(x) &= P(c + iTx), \\ A_{c,T,d}^{-1}F(S) &= F\left(\frac{S - c}{iT}\right). \end{aligned} \quad (\text{RB.26})$$

Substitution also defines an algebra isomorphism on the whole polynomial rings. In particular it sends the principal ideal (χ) onto $(\bar{\chi})$, because $A_\chi = (iT)^q \bar{\chi}$ and the factor $(iT)^q$ is a nonzero scalar unit. Thus the induced quotient map is exactly

$$\hat{A}_{c,T} : \mathbb{C}[S]/(\chi) \longrightarrow \mathbb{C}[x]/(\bar{\chi}), \quad [P] \longmapsto [P(c + iTx)], \quad (\text{RB.27})$$

with inverse induced by the second formula in (RB.26).

Apply (RB.26) to the original division $P = \chi Q + \mathcal{R}_\chi P$. One obtains

$$A_{c,T,2q-1}P = \bar{\chi}((iT)^q A_{c,T,q-1}Q) + A_{c,T,q-1}\mathcal{R}_\chi P. \quad (\text{RB.28})$$

The last term has degree below q . Uniqueness of division gives the exact commuting identity

$$\boxed{\mathcal{R}_{\bar{\chi}} A_{c,T,2q-1} = A_{c,T,q-1} \mathcal{R}_\chi.} \quad (\text{RB.29})$$

For raw jets, set $\lambda_\nu^* = (\zeta_\nu - c)/(iT)$. Let $J_{\chi,d}$ be defined using derivatives in S at ζ_ν , and let $J_{\bar{\chi},d}$ use derivatives in x at λ_ν^* , with the same ordering and multiplicities. Repeated application of the ordinary chain rule gives, for every integer $r \geq 0$,

$$\frac{d^r}{dx^r} P(c + iTx) = (iT)^r P^{(r)}(c + iTx).$$

Define the invertible diagonal map

$$D_T : \bigoplus_\nu \mathbb{C}^{m_\nu} \longrightarrow \bigoplus_\nu \mathbb{C}^{m_\nu}, \quad (v_{\nu,r}) \longmapsto ((iT)^r v_{\nu,r}). \quad (\text{RB.30})$$

The complete raw-jet transport identity is therefore

$$\boxed{J_{\bar{\chi},d} A_{c,T,d} = D_T J_{\chi,d}.} \quad (\text{RB.31})$$

Every scalar $(iT)^r$, including its phase, appears in (RB.30)–(RB.31); the jet coordinates throughout are raw derivatives. Combining (RB.22), (RB.29), and (RB.31) proves preservation of the original raw jets as well as the transformed raw jets.

S27.1.6 6. Exact norm transfer back to the original coordinates

Define a norm on the original polynomial space by the displayed affine transport,

$$\|P\|_{c,T,1} := \|A_{c,T,d}P\|_{1,x}. \quad (\text{RB.32})$$

This definition is independent of the choice of $d \geq \deg P$, because adding zero coefficients does not change the sum. Invertibility of A proves that it is a norm. Equations (RB.19) and (RB.29), under the root-radius hypothesis in (RB.25), yield

$$\|\mathcal{R}_\chi P\|_{c,T,1} \leq C_q \|P\|_{c,T,1}, \quad P \in \mathcal{P}_{2q-1}(S). \quad (\text{RB.33})$$

The same estimate expressed using the untransformed coefficient norm also has fully explicit constants. For $0 \leq j \leq d$, the binomial theorem gives

$$\|A_{c,T,d}S^j\|_{1,x} = (|c| + T)^j, \quad \|A_{c,T,d}^{-1}x^j\|_{1,S} = \left(\frac{1 + |c|}{T}\right)^j. \quad (\text{RB.34})$$

The maximum-column characterization of the coefficient ℓ^1 operator norm, proved after (RB.19), consequently gives the exact operator norms

$$\|A_{c,T,d}\|_{1 \rightarrow 1} = \max\{1, (|c| + T)^d\}, \quad \|A_{c,T,d}^{-1}\|_{1 \rightarrow 1} = \max\left\{1, \left(\frac{1 + |c|}{T}\right)^d\right\}. \quad (\text{RB.35})$$

Thus the original-coordinate estimate is

$$\|\mathcal{R}_\chi P\|_{1,S} \leq C_q \max\left\{1, \left(\frac{1 + |c|}{T}\right)^{q-1}\right\} \max\{1, (|c| + T)^{2q-1}\} \|P\|_{1,S}. \quad (\text{RB.36})$$

Finally, for any $x \in \mathbb{C}$ and any polynomial r of degree below q , the coefficient triangle inequality gives $|r(x)| \leq \|r\|_{1,x} \max\{1, |x|^{q-1}\}$. Applying this to the exact representative in (RB.29) yields

$$|(\mathcal{R}_\chi P)(c + iTx)| \leq C_q \|P\|_{c,T,1} \max\{1, |x|^{q-1}\}. \quad (\text{RB.37})$$

In particular the maximum on the segment $S = c + iTx$, $-1 \leq x \leq 1$, is at most $C_q \|P\|_{c,T,1}$. Equations (RB.24), (RB.27), (RB.29), and (RB.31) specify the exact relation to the original annihilator, quotient, representative, and raw-jet coordinates; no measure or quotient metric is replaced in this coefficient calculation.

S28 The complete corrected endpoint and multiplicity criterion

Source role. Complete corrected PR23 witness with the full multiplicity proof.

S28.1 Sharper endpoint-only criterion and the scope of exterior iteration

This is a mathematical continuation of the supplied Toda and exterior notes. The general Jensen argument and exterior-multiplicity count below have written proofs; they are not additional Lean declarations. The norm-ratio product and overlapping-volume telescope are included in the finite formalization target list. No arithmetic asymptotic bound is claimed.

S28.1.1 1. Eliminate the supremum over recurrence coefficients

Retain a nonempty fixed packet and tensor degree k , cyclic dimension q , the actual positive monic norm sequence ω_N , the actual quotient volume $V_N = \det G_N$, and the source's exact control allowance ϵ_N . Choose consecutive admitted degrees $N=n, \dots, n+r-1$ with $n \geq q$ and integer $r \geq 1$. Put

$$B_{(n,r)} = \log(V_{(n-1)} V_n / (V_{(n+r-1)} V_{(n+r)})),$$

$$A_{(n,r)} = (\omega_{(n+r)} / \omega_n)^{1/(2r)}.$$

These are four endpoint quotient volumes and two endpoint polynomial norms of the existing family. Since V is positive and nonincreasing, $B_{(n,r)} \geq 0$. The source's finite upper bound implies

$$\min_{0 \leq j < r} \epsilon_{(n+j)} \leq A_{(n,r)} \sinh(B_{(n,r)}/(2r)). \quad (E1)$$

Unlike the preceding maximum-recurrence criterion, E1 needs no pointwise upper bound for every recurrence coefficient in the window.

Complete proof For $N=n+j$ set

$$x_j = (1/2) \log(V_{(N-1)}/V_{(N+1)}) \geq 0,$$

$$A_j = \sqrt{\omega_{(N+1)}/\omega_N} > 0.$$

The existing local estimate is $\epsilon_{(n+j)} \leq A_j \sinh(x_j)$. If any $x_j = 0$, the nonnegative allowance at that step is zero, and E1 follows. Otherwise all $x_j > 0$. The function $f(x) = \log(\sinh x)$ has

$$f''(x) = -1/\sinh(x)^2 < 0.$$

Finite Jensen therefore gives

$$\text{product}_j \sinh(x_j) \leq \sinh((\sum_j x_j)/r)^r.$$

Let E be the minimum of the nonnegative allowances. Multiplication of the local bounds gives

$$E^r \leq \text{product}_j \epsilon_{(n+j)} \leq (\text{product}_j A_j) \text{product}_j \sinh(x_j).$$

The actual products telescope:

$$\text{product}_j A_j = (\omega_{(n+r)}/\omega_n)^{1/2},$$

$$2 \sum_j x_j = \log(V_{(n-1)} V_n / (V_{(n+r-1)} V_{(n+r)})).$$

Taking the nonnegative r -th root proves E1. A finite minimum is attained, so E1 selects an actual original degree N inside the specified window. No favorable metric is selected independently, and its original theta representative, quotient and full jets remain attached.

The recurrence product is $\text{VolumeWindow.norm_ratio_product}$; the second telescope is $\text{VolumeWindow.overlapping_log_telescope}$, applied to $V(j)=V_{(n-1+j)}$. The Jensen and nonnegative-root assembly is this written proof rather than a claim about an unimplemented exterior/analytic declaration.

S28.1.2 2. Every input is an endpoint of the two original determinant sequences

The source's $\omega_j = D_{(j+1)}/D_j$ gives

$$A_{(n,r)} = [D_{(n+r+1)} D_{(n)} / (D_{(n+r)} D_{(n+1)})]^{1/(2r)}.$$

The four V -values in B are evaluated by $V_N = D_{(N+1)}/B_{(N-q+1)}$, with the source's literal relation determinant B . All indices are nonnegative because $n \geq q$. No negative-index determinant or inverse of a rank-deficient earlier kernel is used. The common mass factors cancel only in these displayed ratios; the source $\text{norm } \omega_0 = \mu_h^k$ has not been reset.

For the original quartet,

$$q_k = [1 + k(m-1)](k+1)^2, \\ L_{(h,k)} \geq \delta k^2 q_k / 2.$$

The exterior theorem gives $L_{(h,k)} \leq \epsilon_N$ at every admitted N . Thus E1 yields

$$L_{(h,k)} \leq A_{(n,r)} \sinh(B_{(n,r)})/(2r). \quad (E2)$$

A proof that the right side is $o(k^2 q_k)$ along admitted $n=n(k)$, $r=r(k)$ would exclude that fixed off-line quartet. One sufficient set of estimates is

$$r(k) \geq c_h q_k, \quad A_{(n,r)} = O_h(q_k), \\ B_{(n,r)} = O_h(q_k \log k),$$

for $c_h > 0$. Indeed $B/(2r) = o(\log k)$, so $\sinh(B/(2r)) \leq \exp(o(\log k)) = k^{o(1)}$, and the ratio to $k^2 q_k$ tends to zero. These are candidate arithmetic estimates, not consequences of the formal telescope, positivity, the Toda equation, or Deligne's finite-field hypotheses.

The weighted endpoint criterion is sharp as an abstract sequence inequality: equality can occur when all x_j are equal and every $A_j \sinh(x_j)$ equals the same allowance. For arbitrary recurrence sequences the bound is never larger, and potentially strictly smaller, than the bound obtained by replacing $A_{(n,r)}$ by the largest A_j .

S28.1.3 3. A useful boundary on further exterior amplification

The supplied single exterior theorem is correct. It must not be reused with a rank-two hypothesis that no longer holds after exterior powering.

Suppose the original self-adjoint control H has spectrum

$$(+\epsilon, 0 \text{ repeated } q-2 \text{ times}, -\epsilon), \quad \epsilon > 0.$$

On the actual p -th exterior power, $1 \leq p \leq q$, the additive control has $+\epsilon$ and $-\epsilon$ each with multiplicity

$$r_p = \text{binomial}(q-2, p-1),$$

and zero with multiplicity $\text{binomial}(q-2, p) + \text{binomial}(q-2, p-2)$. This follows by the unscaled wedge basis: select the positive direction but not the negative, the negative but not the positive, or both/neither. In particular its operator norm is at most ϵ : it equals ϵ for $1 \leq p \leq q-1$ and is zero for $p=q$. Its rank is $2r_p$, not generally two.

Apply an s -th exterior power to that whole space, whose dimension is $D_p = \text{binomial}(q, p)$. Its largest absolute additive-control eigenvalue is exactly

$\epsilon \min(s, r_p, D_p - s), \quad 0 \leq s \leq D_p.$

Proof: select positive eigenvectors first, zero eigenvectors next, and negative eigenvectors only when the degree forces them. There are r_p available positive directions and r_p negative ones. This attains the stated piecewise maximum; reversing the choices attains its negative. At $s=D_p$ the sum is zero. For example $q=4, p=2$ gives spectrum $(+\epsilon, +\epsilon, 0, 0, -\epsilon, -\epsilon)$, and the next exterior square has allowance 2ϵ .

This does not weaken the original determinant-line amplification or remove its nilpotent arithmetic action. It identifies the precise cost of iterating the operation on the entire exterior space, and prevents a spurious second cost-free amplification. The source's chosen determinant line has its own one-dimensional action and must remain distinguished from the complete first exterior power.

S28.1.4 4. Collaboration boundary

The formal work carries the exact source/quotient determinant and the two loss terms into the original-Gram trace certificate. The analytic collaborator can now estimate the two endpoint quantities in E1, or retain the exact phase and imbalance when the coarse upper bound is too large. The six-part Deligne archive and uploaded ZIP test suites were not opened in this execution environment; the source statements used here came from the complete pasted notes. The current GitHub correction and original source maps are unchanged.

S29.1 Exact consecutive-window control and endpoint determinants

This note proves the consecutive product, its sharper four-endpoint consequence, and its two-transfer reduction for the original canonical quotient metrics. Composed with the independently reviewed arithmetic norm bound on a balanced window, it gives a necessary four-volume growth threshold of **4**, improving the older threshold of 2. It proves no opposing arithmetic upper estimate and no Riemann-hypothesis conclusion. It belongs to the next integration cut, not the frozen Toda-Gamma edition.

S29.1.1 1. Original identity and exact window product

Fix a nonempty reflection-stable packet, tensor degree, cyclic dimension $q \geq 1$, and one admissible observation. Write $V_N = \det G_N > 0$, retain the original monic squared norms $\omega_N > 0$, and set $\delta_N = V_N/V_{N-1} \in (0, 1]$. The original Toda source, TVB.13, TVB.15 and TVB.22–27, supplies

$$\epsilon_N^2 + \phi_N^2 = \frac{\omega_{N+1}}{\omega_N} (1 - \delta_N)(\delta_{N+1}^{-1} - 1), \quad \phi_N = \sigma - \partial_\theta \log V_N, \quad N \geq q. \quad (\text{WP1})$$

The real phase is not set to zero. At a general tilt all norms, volumes and derivatives in WP1 are evaluated at that same tilt. The arithmetic norm and asymptotic composition below use the original observation $\theta = 0$.

For integers $n \geq q, r \geq 1$, put $d_j = \delta_{n+j}$ for $0 \leq j \leq r$, $\Omega = \omega_{n+r}/\omega_n$, and $E = \min_{0 \leq j < r} \epsilon_{n+j}$. Multiplying WP1 first, the norm ratios telescope, every interior $1 - d_j$ occurs twice, and $\prod_{j=1}^r d_j = V_{n+r}/V_n$. Therefore

$$\prod_{j=0}^{r-1} (\epsilon_{n+j}^2 + \phi_{n+j}^2) = \frac{\omega_{n+r} V_n}{\omega_n V_{n+r}} (1 - d_0)(1 - d_r) \prod_{j=1}^{r-1} (1 - d_j)^2. \quad (\text{WP2})$$

Since $E^{2r} \leq \prod_j \epsilon_{n+j}^2 \leq \prod_j (\epsilon_{n+j}^2 + \phi_{n+j}^2)$, dropping only the displayed nonnegative factors, each at most one, gives

$$E \leq \left(\frac{\omega_{n+r} V_n}{\omega_n V_{n+r}} \right)^{1/(2r)}. \quad (\text{WP3})$$

No inverse at degree $q - 2$, reassigned Gram, or recurrence supremum occurs. The empty quotient $q = 0$ is outside this positive-dimensional theorem; its determinant and control are separately the empty determinant and zero.

S29.1.2 2. Sharper four-endpoint bound and comparison

For $r \geq 2$, define

$$\alpha = V_n/V_{n-1}, \quad \beta = V_{n+r}/V_{n+r-1}, \quad t = V_{n+r-1}/V_n, \quad A = \Omega^{1/(2r)}.$$

These are positive and at most one, and the $r - 1$ interior contractions have product t . For $s = r - 1$,

$$\prod_{j=1}^s (1 - d_j) \leq (1 - t^{1/s})^s. \quad (\text{WP4})$$

If any interior $d_j = 1$, the left side is zero. Otherwise set $v_j = -\log d_j > 0$. The second derivative of $f(v) = \log(1 - e^{-v})$ is $-e^{-v}/(1 - e^{-v})^2 < 0$, so finite concavity proves WP4. This is ordinary Jensen concavity, obtainable from the integral form by a step function; see [DLMF §1.7\(iv\)](#). Inserting WP4 into WP2 gives

$$E \leq U := A \left(\frac{(1 - \alpha)(1 - \beta)}{\beta t} \right)^{1/(2r)} \left(1 - t^{1/(r-1)} \right)^{(r-1)/r}. \quad (\text{WP5})$$

For $r = 1$ use the separate expression

$$E = \epsilon_n \leq \sqrt{\frac{\omega_{n+1}}{\omega_n} (1 - \alpha)(\beta^{-1} - 1)}. \quad (\text{WP6})$$

No $1/(r - 1)$ is evaluated in WP6. For any r , a unit contraction $d_j = 1$ makes an adjacent local radius sum zero; hence the corresponding allowance and phase both vanish and $E = 0$. At an interior unit contraction both neighboring local sums vanish. If $t = 1$, all interior contractions are one and WP5 is zero.

The corrected PR23 endpoint note proves the older bound

$$E \leq A \sinh\left(\frac{\mathcal{B}}{2r}\right), \quad \mathcal{B} = \log \frac{V_{n-1}V_n}{V_{n+r-1}V_{n+r}} = -\log \alpha - \log \beta - 2 \log t.$$

In fact $U \leq A \sinh(\mathcal{B}/(2r))$. To prove it without assuming an arithmetic extremizer, replace just the interior scalar contractions by their common geometric mean. This maximizes the exact product by WP4 while leaving the four endpoints fixed. For that scalar sequence put $v_j = -\log d_j$. The original local completion of the square is

$$(1 - d_j)(d_{j+1}^{-1} - 1) = \sinh^2 \frac{v_j + v_{j+1}}{2} - \left(e^{(v_{j+1} - v_j)/2} - \cosh \frac{v_j + v_{j+1}}{2} \right)^2.$$

Drop this square and apply concavity of $\log \sinh x$, whose second derivative is $-1/\sinh^2 x$, to the r nonnegative half-sums. Their sum is $\mathcal{B}/2$, proving the comparison. A zero half-sum is handled before logarithms. WP5 also dominates the simpler WP3 because all factors it retains are at most one; WP3 alone need not dominate the older bound for small contractions.

For constant $d = e^{-v} < 1$, WP5 becomes $2A \sinh(v/2)$, whereas the older expression is $A \sinh v$; their ratio is $\cosh(v/2)$.

The sharpness claim is only for the relaxed scalar data, not the arithmetic moment family. In its strictly positive case require **all three** $\alpha < 1, \beta < 1, t < 1$. Set the interior ratios equal, put $f_j = (1 - d_j)(d_{j+1}^{-1} - 1) > 0$, choose successive norm ratios U^2/f_j , phases zero and all allowances U . The norm-ratio product is exactly Ω , so the prescribed endpoints and equality hold. Zero-product cases give a zero bound directly. Strict contraction of only the two outside ratios would not justify claiming $f_j > 0$ when $t = 1$.

S29.1.3 3. Retained phase and interior loss

When every interior contraction is strictly below one, define

$$J = (r - 1) \log(1 - t^{1/(r-1)}) - \sum_{j=1}^{r-1} \log(1 - d_j) \geq 0.$$

WP2 is precisely

$$\prod_j (\epsilon_{n+j}^2 + \phi_{n+j}^2) = U^{2r} e^{-2J}, \quad \prod_j (E^2 + \phi_{n+j}^2) \leq U^{2r} e^{-2J}. \quad (\text{WP7})$$

The polynomial $P(x) = \prod_j (x + \phi_{n+j}^2)$ is strictly increasing for $x \geq 0$. For consistent input, the right side R is at least $P(0)$, so $P(x) = R$ has a unique nonnegative solution x_* and $E \leq \sqrt{x_*}$. If proposed data instead have $R < P(0)$, they are inconsistent with the original radius identities; a nonnegative threshold cannot then be asserted. Unit-contraction cases are handled directly, without using an infinite or undefined J .

S29.1.4 4. Literal determinant and full-jet transfer cancellation

To distinguish this scalar from the existing exterior map named Λ_N , write $\Lambda_N^{\text{sc}} = \omega_N / V_N$. With the unchanged source and relation determinants, TVB.13 and TVB.15 give

$$\omega_N = \mathfrak{D}_{N+1} / \mathfrak{D}_N, \quad V_N = \mathfrak{D}_{N+1} / \mathfrak{B}_{N-q+1}, \quad \boxed{\Lambda_N^{\text{sc}} = \mathfrak{B}_{N-q+1} / \mathfrak{D}_N}. \quad (\text{WP8})$$

The ordinary monic recurrence and moment-determinant background is [DLMF §18.2\(iv\)](#) and [§18.2\(ix\)](#); the specific arithmetic relation determinant is the supplied construction, not a conclusion attributed to DLMF. Thus WP3 equals

$$E \leq \left(\frac{\Lambda_{n+r}^{\text{sc}}}{\Lambda_n^{\text{sc}}} \right)^{1/(2r)} = \left(\frac{\mathfrak{B}_{n+r-q+1} \mathfrak{D}_n}{\mathfrak{D}_{n+r} \mathfrak{B}_{n-q+1}} \right)^{1/(2r)}. \quad (\text{WP9})$$

PR24's complete transfer note, equations (4)–(5), defines F_a using raw derivatives of the real monic source polynomials at every doubled root multiplicity, with fixed row order. It proves

$$V_N = \left(\prod_{j=a}^N \omega_j \right) \frac{\det V}{\det F_a}, \quad a = N - q + 1.$$

Consequently, setting now $a = n - q + 1$,

$$\boxed{E \leq \left[\frac{\det F_{a+r}}{\det F_a} \prod_{j=0}^{q-2} \frac{\omega_{a+j}}{\omega_{a+r+j}} \right]^{1/(2r)}}. \quad (\text{WP10})$$

This uses two transfer determinants; at $q = 1$ the norm product is empty. The common raw confluent Vandermonde, including every derivative factorial and its coordinate phase, cancels through the displayed ratio. No absolute value is inserted: positivity follows from equality with the positive scalar ratio in WP9. The relation map still contains the unit i^q , and F_0 need not equal V , although their determinants agree.

Literal mass bookkeeping confirms the cancellation: rescaling the fixed measure by $c > 0$ would give $\omega_N \mapsto c\omega_N$, $V_N \mapsto c^q V_N$, $\Lambda_N^{\text{sc}} \mapsto c^{1-q} \Lambda_N^{\text{sc}}$. Only the endpoint ratio is invariant. No such rescaling is performed here.

S29.1.5 5. Immediate arithmetic consequence: threshold four

The complete Arithmetic Endpoint Bounds note proves its original lower convolution envelope and exact general norm-window bound, equations (29), (33), (34), (37). Its independently checked balanced extension yields

$$A_{h,k,n,r} \leq C_h^{\text{bal}} n, \quad n \geq k \geq 3, \quad n/2 \leq r \leq n,$$

where, with $b \in (0, \pi/2)$, $B_h = 42 + 2 \deg h$, $X_h = \max(1, M_h(b), M_h(-b))$, $K_h = \max(1, \vartheta_h^{-1})$,

$$C_h^{\text{bal}} = 256e^\pi \max(1, 3/c_h) X_h K_h \max(1, b^{-3}) 6^{B_h/3}. \quad (\text{WP11})$$

The constant is finite and depends only on the fixed packet and chosen b ; it is not a numerically enclosed constant. A direct check of the extension uses $\mathfrak{I}_n(n) \geq 2n^{2n+1}/((2n+1)4^n)$, $(2(n+r))! \leq (4n)^{2(n+r)}$, and the two moment masses before taking roots. The factorial/Legendre contribution becomes $4n 8^{n/r} ((2n+1)/(c_h n))^{1/(2r)} \leq 256n \max(1, 3/c_h)$. The remaining factors are bounded by $X_h K_h \max(1, b^{-3}) e^\pi 6^{B_h/3}$, using $2r \geq n$ and decreasing $\log(2n)/n$ for $n \geq 3$.

For a packet consisting exactly of a hypothetical full off-line quartet of common multiplicity m , the original exterior lower allowance satisfies

$$q = q_k = [1 + k(m-1)](k+1)^2, \quad L_{h,k} \geq \delta k q / 2 > 0, \quad L_{h,k} \leq \epsilon_N.$$

Choose $n = q$, $r = q - 1$. Here $q \geq k \geq 3$, the allowance indices are precisely $q, \dots, 2q - 2$, and the last norm/volume endpoint is $2q - 1$. WP3 and WP11 imply

$$C_k := \log \frac{V_q}{V_{2q-1}} \geq 2(q-1) \log \frac{\delta k}{2C_h^{\text{bal}}}. \quad (\text{WP12})$$

The old four-volume budget obeys the exact decomposition

$$\mathcal{B}_{h,k} = \log \frac{V_{q-1}V_q}{V_{2q-1}V_{2q}} = 2C_k + \log \frac{V_{q-1}}{V_q} + \log \frac{V_{2q-1}}{V_{2q}} \geq 2C_k.$$

Therefore

$$\boxed{\mathcal{B}_{h,k} \geq 4(q_k - 1) \log \frac{\delta k}{2C_h^{\text{bal}}}, \quad \liminf_{k \rightarrow \infty} \frac{\mathcal{B}_{h,k}}{q_k \log k} \geq 4.} \quad (\text{WP13})$$

The diagonal window also gives $\liminf \log(V_q/V_{2q})/(q_k \log k) \geq 2$. These lower bounds follow from the actual arithmetic norm estimate and original radius identities, not from scalar-fixture sampling. The old threshold 2 remains a valid weaker result. A separately proved $\limsup \mathcal{B}_{h,k}/(q_k \log k) < 4$ would now contradict the hypothetical quartet; **no such upper bound is established**. Equivalently, WP9 identifies the sufficient target $(2r)^{-1} \log(\Lambda_{n+r}^{\text{sc}}/\Lambda_n^{\text{sc}}) - \log(kq_k) \rightarrow -\infty$, but does not prove that target for the arithmetic family.

S29.1.6 6. Exact fixture and verification scope

The independently recomputed fixture is $d\mu = 7e^{-u^2/2} du/\sqrt{2\pi}$, $\chi = u^2 + 1$, $Q_{j+1} = uQ_j - jQ_{j-1}$, $\omega_j = 7j!$, and $G_N = (\sum_{j \leq N} [Q_j][Q_j]^T/\omega_j)^{-1}$. It gives exactly

$$G_2 = \text{diag}(7/3, 7), \quad G_3 = \text{diag}(7/3, 21/11), \quad G_4 = \text{diag}(42/43, 21/11), \\ (\epsilon_2^2, \epsilon_3^2, \epsilon_4^2) = (16/3, 400/99, 4225/946), \quad (V_1, \dots, V_5) = (49, 49/3, 49/11, 882/473, 980/1333).$$

For $n = 2, r = 3, \Omega = 60, \alpha = 1/3, \beta = 110/279, t = 54/473$. The minimum, geometric mean, sharper bound and older bound are respectively approximately 2.0100756305184, 2.1407199197265, 2.1666731523012 and 2.5178436563897. Their exact underlying quantities, not these decimal strings, enter the identity checks.

A separate original exponential tilt $\theta = 1/2$ retains mass $7e^{1/8}$. At degree 2 it gives $\phi_2 = 7/129 \neq 0$ and $\epsilon_2^2 = 18769/4128$; further nonzero phases, the independent derivative $\sigma - \partial_\theta \log V_N$, and the whole window product are checked. The polynomial $u^2 - 3$ supplies an actual interior unit contraction. A one-dimensional quotient tests zero control with potentially nonzero phase and the empty norm band in WP10. Raw derivatives at doubled nonreal nodes independently verify WP8–WP10, while the literal moment matrices verify the source/relation determinants.

The receipt separates exact symbolic/rational/data checks from four approximate decimal-display comparisons. Symbolic product factorizations were checked for $r = 1, \dots, 8$; rational phases and degeneracies, exact powered endpoint comparisons, mass scaling, full raw-jet transfers and balanced-window index/algebra checks are retained. These finite checks do not replace the written general proofs, are not arithmetic zero packets, and are not interval or Lean certificates. No Wolfram session was run or its reported execution adopted as independent evidence.

The complete submitted calculation, original TVB source sections used above, corrected PR23 endpoint note, complete PR24 transfer note, complete Arithmetic Endpoint Bounds note, balanced-window proof, and parent four-volume synthesis were read. Their immutable hashes are in EXACT_VERIFICATION_RECEIPT.json; no private attachment path occurs in the public derivative or receipt. Source attachments remain unchanged. The parent's FOUR_VOLUME_THRESHOLD.md was independently approved at SHA-256 9ff55c84d74db85306e7a68c70fe7b08d8e642e8ac1a3e6137649f68e102fc3a.

Selecting the finite minimizing degree keeps the existing representative $R_N, J^{(k)}R_N = \eta_{h,k}$, and $q^{(k)}R_N = \sigma_h^{\otimes k} \eta_{h,k}$, with the same arithmetic unit, jets, cohomology classes and supported-zero/absence distinction. Endpoint data certify existence, not identification of the minimizing degree. No owner scalar-budget optimization, canonical source, frozen edition, or remote publication was changed by this review.

Canonical restriction and the arithmetic endpoint volume

S30.1 1. Result, inherited input, and scope

The remaining quantity in the current endpoint criterion is a ratio of four canonical arithmetic quotient volumes. This note constructs its underlying restriction operator, proves composition and action identities for that operator, and gives two further ways to calculate and bound the same volume. No new arithmetic metric is selected.

The principal map is

$$T_{i,j} : (E, G_j) \longrightarrow (E, G_i), \quad T_{i,j} = K_i G_j, \quad K_n = G_n^{-1}, \quad i \leq j. \quad (1)$$

It is the **metric adjoint of the original arithmetic identity transport** from degree i to degree j . It is also the map read by restricting the actual degree- j canonical polynomial representative to degrees at most i :

$$R_i T_{i,j} = \text{pr}_{\leq i} R_j. \quad (2)$$

The source coordinate inclusions in (2) are made explicit below. The return maps compose in the reverse direction,

$$T_{i,j} T_{j,l} = T_{i,l}, \quad \det T_{i,j} = V_j / V_i, \quad V_n = \det G_n. \quad (3)$$

Their eigenvalues $g_{i,j,a}$ are in $(0, 1]$ and have an exact source meaning: they are the squared singular values of the original identity transport equipped with its two actual quotient metrics, and also of the polynomial restriction on the canonical image. Hence

$$\log(V_i / V_j) = - \sum_{a=1}^{\dim E} \log g_{i,j,a}. \quad (4)$$

No arithmetic vector is killed by $T_{i,j}$ at a finite admitted degree. Its small eigenvalues quantify the cost of recovering the original arithmetic coordinates from a lower-degree portion of their representatives.

The new finite upper bounds express (4) through positive traces of powers of $I - T_{i,j}$, with an explicitly certified lower bound on $g_{i,j,a}$. A Cauchy–Binet expansion gives another exact representation, by nonnegative full-jet minor weights. The expansion retains the literal mass of the arithmetic source and does not assign its total weight the value one.

The preceding analytic continuation proved, for a fixed full packet h and $n \geq k \geq 3$,

$$\left(\frac{\omega_{h,k,2n}}{\omega_{h,k,n}} \right)^{1/(2n)} \leq C_h n. \quad (5)$$

We use this as an inherited written analytic theorem, not as a newly kernel-checked result. Composing the new upper certificates with that theorem and the formalizer's endpoint criterion gives an explicit control certificate for the original family.

For a packet consisting exactly of an off-line quartet, the already-established endpoint lower bound additionally implies the following new representative-level consequence: among the two indicated degree restrictions, at least one squared singular value is at most

$$\exp \left[-\operatorname{arsinh} \left(\frac{\delta k}{2C_h} \right) \right]. \quad (6)$$

This is a necessary consequence of an off-line quartet, not an assertion that small singular values imply one. The calibration below retains a nilpotent on-line block with nontrivial restriction loss.

The general matrix and exterior mechanisms are classical. The contribution is their explicit propagation through this programme's actual source, full-jet quotient, support transitions, and arithmetic action. No upper estimate uniform in k for the logarithmic loss is proved in this note.

S30.2 2. Preserve the original base and source

Retain the marked coefficient square

$$\begin{array}{ccc} G(\mathbb{Z}) & \xrightarrow{G(j)} & G(\mathbb{C}) \\ p_{\mathbb{Z}} \downarrow & & \downarrow p_{\mathbb{C}} \\ \mathbb{Z} & \xrightarrow{j} & \mathbb{C}. \end{array} \quad (7)$$

Here $G(R) = \{\tau\} \sqcup \{r^\bullet : r \in R\}$, $e_R = 0_R^\bullet$, and $p_R(\tau) = 0_R$, $p_R(r^\bullet) = r$. The target of $p_{\mathbb{Z}}$ is infinite. The structural base remains $\mathfrak{b}_\tau$. Polynomial degree and relation depth do not adjoin another scalar zero.

Keep

$$C_+ = [V \xrightarrow{\Theta} \mathcal{B}], \quad Q = \mathcal{B}/\Theta V, \quad D = -x\partial_x, \quad g = 2\xi. \quad (8)$$

For a fixed finite packet, retain every selected zero with its complete order:

$$h(s) = \prod_{\rho \in Z} (s - \rho)^{m_\rho}, \quad v_h = g/h, \quad \mathcal{M}F_h = v_h. \quad (9)$$

The arithmetic integration density at tensor degree k is

$$w_h(t) = \frac{|v_h(1/2 + it)|^2}{2\pi}, \quad m_{h,k} = w_h^{*k}, \quad \mu_h = \int w_h, \quad \int m_{h,k} = \mu_h^k. \quad (10)$$

On the existing cyclic sum module use

$$E = \mathbb{C}[S]/(\chi_{h,k}), \quad q = \deg \chi_{h,k}, \quad A = M_S, \quad S = s_1 + \cdots + s_k, \quad c = k/2. \quad (11)$$

The canonical arithmetic source is

$$\mathcal{V}P = P(D_1 + \cdots + D_k)(F_h^{\otimes k}), \quad (12)$$

and its norm is

$$\|\mathcal{V}P\|^2 = \int_{\mathbb{R}} |P(c + iu)|^2 m_{h,k}(u) du. \quad (13)$$

The full arithmetic coefficient maps remain

$$J^{(k)}\mathcal{V} = \eta\pi_\chi, \quad q^{(k)}\mathcal{V} = \sigma_h^{\otimes k}\eta\pi_\chi, \quad \eta[P] = v_h^{\otimes k}P(A_k)1, \quad v_h = j_h(g/h). \quad (14)$$

All derivatives and arithmetic units in these jets remain. The quotient coordinate $[P]_\chi$ and its arithmetic image $\eta[P]_\chi$ are connected by this specified injective module map.

Let $p_0, p_1, \dots$ be the original monic S -polynomials orthogonal for (13), with squared norms $\omega_n > 0$. In particular $\omega_0 = \mu_h^k$. No polynomial is divided by its norm.

For $N \geq q - 1$, let

$$\mathcal{P}_N = \mathbb{C}[S]_{\leq N}, \quad \mathcal{D}_N = \chi \mathcal{P}_{N-q}, \quad \mathcal{P}_{-1} = 0. \quad (15)$$

The exact source sequence is

$$0 \longrightarrow \mathcal{P}_{N-q} \xrightarrow{\times \chi} \mathcal{P}_N \xrightarrow{\pi_\chi} E \longrightarrow 0. \quad (16)$$

Monicity proves surjectivity and the displayed kernel, including at $N = q - 1$. Under $\mathcal{V}$, the relation χP is the same original theta boundary whose primitive was constructed by fixed-order division into the tensor factors. Its support label and both occurrences of every Koszul sign remain in that primitive.

All finite Gram inverses in the note require $q \geq 1$. For $h = 1$ the finite arithmetic packet is zero, all displayed determinant-line observations have empty determinant one, and no positive-rank inverse is introduced. Its analytic source and mass remain as in (10).

S30.3 3. Construct the canonical degree transport and its adjoint

Use the ordered, unscaled basis $(p_0, \dots, p_N)$ of $\mathcal{P}_N$. Define

$$O_N = \text{diag}(\omega_0, \dots, \omega_N), \quad B_N = [b_0, \dots, b_N], \quad b_n = [p_n]_\chi. \quad (17)$$

Here $B_N : \mathbb{C}^{N+1} \rightarrow E$ is the remainder map in the fixed quotient basis $1, S, \dots, S^{q-1}$. Put

$$K_N = B_N O_N^{-1} B_N^*, \quad G_N = K_N^{-1}, \quad R_N = O_N^{-1} B_N^* G_N : E \rightarrow \mathcal{P}_N. \quad (18)$$

The formula gives

$$B_N R_N = I_E, \quad R_N^* O_N R_N = G_N, \quad \text{im } R_N = \mathcal{D}_N^\perp. \quad (19)$$

Indeed B_N is onto, so K_N is positive definite. For $z \in \ker B_N$, $z^* O_N R_N = z^* B_N^* G_N = 0$. Every representative is $R_N u + z$; the two summands are orthogonal. Thus (18) is the unique minimum-norm representative for the original relation space, not an independently selected form.

The actual test-function representative is $\mathcal{V} R_N$. Every identity involving R_N below passes to that source by (12)–(14).

For $i \leq j$, let $L_{i,j} : \mathcal{P}_i \hookrightarrow \mathcal{P}_j$ be coefficient padding and let $P_{i,j} : \mathcal{P}_j \rightarrow \mathcal{P}_i$ keep exactly the first $i + 1$ monic coordinates. Since the full monic family is orthogonal, this is the orthogonal projection onto the original lower-degree source. One has

$$B_j L_{i,j} = B_i, \quad L_{i,j}^* O_j L_{i,j} = O_i. \quad (20)$$

Let $\mathcal{E}_N$ denote E with its actual quotient metric G_N . The original quotient transport is

$$I_{i,j} : \mathcal{E}_i \rightarrow \mathcal{E}_j, \quad u \mapsto u, \quad B_j L_{i,j} = I_{i,j} B_i. \quad (21)$$

It intertwines A exactly. Its Gram decreases, because the larger source admits the old representative and additional original relations:

$$G_j \preceq G_i. \quad (22)$$

Its metric adjoint is the map in (1). To prove it, compute

$$\langle I_{i,j} u, v \rangle_{G_j} = u^* G_j v = u^* G_i (K_i G_j v) = \langle u, T_{i,j} v \rangle_{G_i}. \quad (23)$$

This is an adjoint of the **existing** transport. It is not asserted to be a unital algebra homomorphism.

Direct substitution into (18) proves the representative restriction identity

$$\boxed{L_{i,j}R_iT_{i,j} = P_{i,j}R_j.} \quad (24)$$

For example, the first $i + 1$ coordinates of R_j are $O_i^{-1}B_i^*G_j$; the right coordinates of $R_iT_{i,j}$ are $O_i^{-1}B_i^*G_iK_iG_j$, which are identical.

The adjoints compose exactly:

$$T_{i,j}T_{j,l} = K_iG_jK_jG_l = K_iG_l = T_{i,l}. \quad (25)$$

This agrees with contravariance of metric adjoints applied to the original identity transports. There is no intervening choice of a metric.

S30.4 4. Record the arithmetic action and the actual boundary correction

Set

$$H_N = G_N^{-1}(A^*G_N + G_NA - kG_N), \quad W_N = A^*G_N + G_NA - kG_N, \quad V_N = AK_N + K_NA^* - kK_N. \quad (26)$$

The adjoint-action identity gives

$$\boxed{AT_{i,j} - T_{i,j}A = H_iT_{i,j} - T_{i,j}H_j = V_iG_j - K_iW_j.} \quad (27)$$

For a direct proof, expand the rightmost expression and cancel the two occurrences of $K_iA^*G_j$ and of kK_iG_j . This records the full equivariance defect of the return map. The forward transport (21) is equivariant. The return need not be equivariant for the arithmetic action.

If ϵ_i, ϵ_j are the actual operator norms of H_i, H_j in their respective metrics, (22)–(23) imply the finite bound

$$\|AT_{i,j} - T_{i,j}A\|_{\mathcal{E}_j \rightarrow \mathcal{E}_i} \leq \epsilon_i + \epsilon_j. \quad (28)$$

No spectral subspace of the return map is therefore declared invariant under A merely because it is a useful metric diagnostic. Equation (27) is the explicit comparison.

Define the degree-restriction loss endomorphism

$$H_{i,j} = I_E - T_{i,j} = (K_j - K_i)G_j. \quad (29)$$

The original relation correction is

$$\boxed{\mathfrak{d}_{i,j} = L_{i,j}R_i - R_j = L_{i,j}R_iH_{i,j} - (I - P_{i,j})R_j.} \quad (30)$$

Both terms on the right have arithmetic remainder $H_{i,j}$. Their difference has zero remainder. Consequently

$$B_j\mathfrak{d}_{i,j} = 0, \quad \text{im } \mathfrak{d}_{i,j} \subseteq \mathcal{D}_j \cap \mathcal{D}_i^\perp, \quad \mathfrak{d}_{i,j}^*O_j\mathfrak{d}_{i,j} = G_i - G_j. \quad (31)$$

The Gram identity follows because R_j is orthogonal to every relation in $\mathcal{D}_j$. Thus the lower-degree canonical representative is the higher-degree representative plus the explicit original relation (30).

The split map of a single active fibre is

$$\begin{aligned} I_{i,j}^\tau : \mathcal{E}_i^\tau &\rightarrow \mathcal{E}_j^\tau, & u^\bullet &\mapsto u^\bullet, & \tau &\mapsto \tau, \\ T_{i,j}^\tau : \mathcal{E}_j^\tau &\rightarrow \mathcal{E}_i^\tau, & u^\bullet &\mapsto (T_{i,j}u)^\bullet, & \tau &\mapsto \tau. \end{aligned} \quad (32)$$

These are $G(\mathbb{C})$ -linear single-fibre maps. The forward maps embed into the original directed support diagram. The reverse maps are the metric-adjoint diagram; an additional naturality across the original forward transports is not presumed. Their actual reverse-composition identity is (25). Inclusion of a single-fibre lift into the reconstructed carrier sends $u^\bullet$ to (ℓ_N, u) and its external τ to the carrier's external zero.

Under the original degree- j internal quotient, a supported value of $\mathfrak{d}_{i,j}$ becomes $(\ell_j, 0)$; external absence remains external absence. The relation before that map remains available in (30)–(31), including its original theta primitive.

S30.5 5. Exact volume as a restriction spectrum

The endomorphism $T_{i,j}$ is positive self-adjoint in both G_i and G_j :

$$G_i T_{i,j} = G_j, \quad G_j T_{i,j} = G_j K_i G_j. \quad (33)$$

Also $0 \prec T_{i,j} \preceq I$ in either metric. For G_i , this is (22); for G_j , use $K_i \preceq K_j$. Let its q eigenvalues, with multiplicities, be $g_a \in (0, 1]$.

The singular values of $I_{i,j} : \mathcal{E}_i \rightarrow \mathcal{E}_j$ are exactly $\sqrt{g_a}$ because $I_{i,j}^\dagger I_{i,j} = T_{i,j}$. The same nonzero singular values belong to $T_{i,j}$ in the reverse Hilbert types and to the source restriction (24). This is the concrete principal-angle construction for the canonical image and the lower-degree source; it uses their actual inner products.

Taking determinants gives

$$\boxed{\det T_{i,j} = \frac{\det K_i}{\det K_j} = \frac{V_j}{V_i}, \quad \mathcal{L}_{i,j} := \log \frac{V_i}{V_j} = - \sum_a \log g_a.} \quad (34)$$

The top exterior map $\bigwedge^q T_{i,j}$ acts by this literal determinant in the fixed determinant coordinates. With the source's unscaled alternating tensor representative, the determinant vector has squared norm $q! V_N$ at degree N . Both factorials remain in the ratio. This is determinant-line accounting through the same source-relation sequence as in the previous Deligne-oriented construction, not an imported purity conclusion.

An equivalent exact count is

$$\boxed{\mathcal{L}_{i,j} = \int_0^1 \frac{\#\{a : g_a < t\}}{t} dt = \int_0^\infty \#\{a : g_a < e^{-s}\} ds.} \quad (35)$$

For one $g \in (0, 1]$, the first integral is $\int_g^1 dt/t$; summing proves the formula. The second uses $t = e^{-s}$. Values at equality do not affect the integrals.

For the quartet endpoint window, (34) is applied twice, to

$$(i_0, j_0) = (q-1, 2q-1), \quad (i_1, j_1) = (q, 2q). \quad (36)$$

Their losses add to the original four-volume quantity $\mathcal{B}_{h,k}$.

S30.6 6. An exterior expansion retains every full-jet basis weight

For a q -element subset $D = \{d_1 < \dots < d_q\} \subseteq \{0, \dots, j\}$ define

$$a_D = \frac{|\det[b_{d_1}, \dots, b_{d_q}]|^2}{\prod_{d \in D} \omega_d}. \quad (37)$$

Cauchy–Binet applied to (18) gives

$$\boxed{\det K_j = \sum_{|D|=q} a_D.} \quad (38)$$

This is an identity of positive finite scalar observations, with no assignment of the sum to one. The actual exterior map giving the numerator is

$$\bigwedge^q B_j : \bigwedge^q \mathcal{P}_j \rightarrow \det E, \quad p_{d_1} \wedge \dots \wedge p_{d_q} \mapsto \det[b_{d_1}, \dots, b_{d_q}] e_0 \wedge \dots \wedge e_{q-1}. \quad (39)$$

The squared norm of the source wedge is $\prod_{d \in D} \omega_d$. The determinant-coordinate line used to read its coefficient is specified; it is not the canonical arithmetic Gram reset to the identity.

Introduce the finite scalar polynomial

$$Z_{i,j}(z) = \det(K_i + z(K_j - K_i)). \quad (40)$$

Multilinearity and Cauchy–Binet prove the full coefficient identity

$$Z_{i,j}(z) = \sum_{|D|=q} a_D z^{\#(D \cap \{i+1, \dots, j\})}. \quad (41)$$

In particular $Z(0) = \det K_i > 0$, $Z(1) = \det K_j$, and

$$\frac{Z_{i,j}(z)}{\det K_j} = \det(T_{i,j} + zH_{i,j}) = \prod_a (g_a + z(1 - g_a)). \quad (42)$$

The scalar division is the displayed observation map from the retained pair $(Z, \det K_j)$; the original total and mass remain in (38)–(41). This determinant generating mechanism is classical in projection determinantal measures. Its present interpretation concerns the original degree-admission and full-jet maps, not a randomly selected alternative arithmetic source.

The first two occupation ratios are

$$\frac{Z'(1)}{Z(1)} = \text{Tr } H_{i,j}, \quad \frac{Z''(1) + Z'(1)}{Z(1)} - \left(\frac{Z'(1)}{Z(1)} \right)^2 = \text{Tr}(H_{i,j} - H_{i,j}^2). \quad (43)$$

These identities follow by differentiating (42); every denominator is the original positive scalar total. The weighted counts in (41) remain available before taking those ratios.

There are two explicit ways a term can be missing from a scalar total. An admitted subset with dependent full-jet columns has $a_D = 0$, a supported zero. A subset containing an index above the admitted degree is outside that finite indexing object, and its extension to a larger indexing object is assigned external absence. For example, in the calibration $\chi = (S - 1)^2$, b_0 and b_2 are dependent: the subset $\{0, 2\}$ is admitted and has supported zero weight. The subset $\{0, 4\}$ is absent from degree three. The algebraic specialization $z = 0$ in (41) sends each positive-degree monomial to a supported scalar zero; its support record is not retroactively deleted.

Full derivatives are retained under a change to raw confluent jet coordinates. For roots λ_a of orders m_a , let

$$C_{\chi(a,r),b} = \partial_S^r S^b|_{S=\lambda_a} = \begin{cases} \frac{b!}{(b-r)!} \lambda_a^{b-r}, & b \geq r, \\ 0, & b < r. \end{cases} \quad (44)$$

Its determinant, in the stated block order, is

$$\det C_\chi = \left(\prod_a \prod_{r=0}^{m_a-1} r! \right) \prod_{a < b} (\lambda_b - \lambda_a)^{m_a m_b}. \quad (45)$$

For any explicitly retained invertible arithmetic unit matrix M_u , the quotient-coordinate change is $C_\chi M_u$. Every weight (37) acquires the same factor $|\det(C_\chi M_u)|^2$, both totals acquire it, and (34), (42) are unchanged through that specified ratio. The action and return are conjugated by this matrix, and the canonical representative is precomposed with its inverse. No nilpotent derivative order is removed.

For the actual cyclic inclusion $\eta : E \hookrightarrow B_k^{S_k}$, the ambient matrix can be rectangular. Its correct exterior comparison is

$$\bigwedge^q (\eta B_D) = (\det B_D) \left(\bigwedge^q \eta \right) (e_0 \wedge \cdots \wedge e_{q-1}).$$

The fixed nonzero image vector is retained. There is no determinant of a rectangular matrix being inverted. A square coordinate change $C_\chi M_u$ applies only on a specified coordinate model of the finite image, or for an actual unit endomorphism of E . In the ambient symmetric module the original map remains η , including the complete factor $v_h^{\otimes k}$.

S30.7 7. A certified finite logarithmic upper bound

Let $H = H_{i,j}$ and $s_m = \text{Tr}(H^m)$. Positivity in the original metric implies $s_m \geq 0$, and the eigenvalues lie in $[0, 1)$. Therefore

$$\mathcal{L}_{i,j} = \sum_{m=1}^{\infty} \frac{s_m}{m}. \quad (46)$$

A valid rational or real lower gap $g_0 > 0$ is supplied by the **actual matrix inequality**

$$K_i \succeq g_0 K_j. \quad (47)$$

It gives $H \preceq (1 - g_0)I$ in G_j . Let $r = 1 - g_0$. For integer $p \geq 1$ and $0 < r < 1$, set

$$c_p(r) = \frac{-\log(1-r) - \sum_{m=1}^p r^m/m}{r^{p+1}}. \quad (48)$$

The finite enclosure is

$$\sum_{m=1}^p \frac{s_m}{m} \leq \mathcal{L}_{i,j} \leq U_p(H, g_0) := \sum_{m=1}^p \frac{s_m}{m} + c_p(r)s_{p+1}. \quad (49)$$

For $r = 0$, (47) and $K_i \preceq K_j$ give $H = 0$ and both bounds are zero.

Proof. For $0 \leq x \leq r$, the tail of $-\log(1-x)$ is

$$x^{p+1} \sum_{m=p+1}^{\infty} \frac{x^{m-p-1}}{m} \leq x^{p+1} \sum_{m=p+1}^{\infty} \frac{r^{m-p-1}}{m} = c_p(r)x^{p+1}.$$

Apply this scalar inequality to the positive self-adjoint H and take its trace. For every fixed admitted pair and fixed certified g_0 , the lower and upper bounds converge to the same loss as $p \rightarrow \infty$. This is fixed-pair convergence, not a uniform assertion in tensor degree.

Already $p = 1$ gives

$$\mathcal{L}_{i,j} \leq s_1 + \frac{-\log g_0 - (1 - g_0)}{(1 - g_0)^2} s_2. \quad (50)$$

It retains a second moment rather than replacing every loss by the maximum one. Higher p retain the successive moments of the same operator. No eigenvalue of A is inferred from an eigenvalue of H ; their actual commutator is (27).

For the two windows in (36), verified gaps $g_0^{(0)}, g_0^{(1)}$ give

$$\mathcal{B}_{h,k} \leq U_p(H^{(0)}, g_0^{(0)}) + U_p(H^{(1)}, g_0^{(1)}). \quad (51)$$

Combining (5), the formalizer's endpoint theorem, and monotonicity of $\sinh$ gives the finite canonical-family estimate

$$\min_{q \leq N < 2q} \epsilon_{h,k,N} \leq C_h q \sinh \left(\frac{U_p(H^{(0)}, g_0^{(0)}) + U_p(H^{(1)}, g_0^{(1)})}{2q} \right), \quad q \geq k \geq 3. \quad (52)$$

This theorem uses the explicit matrix certificate (47). Existence of some positive gap for each finite pair does not imply the uniform gap or moment control that would finish the arithmetic argument. Formula (52) states exactly the quantity a certified finite or uniform analytic estimate must bound.

S30.7.1 Error-aware certificate types

The checker supplies exact rational lower and upper bounds for $\log x$ on positive rational inputs. It uses $x = 2^e y$, $1 \leq y < 2$, and

$$\log y = 2 \sum_{a=0}^{m-1} \frac{t^{2a+1}}{2a+1} + \mathcal{E}_m, \quad t = \frac{y-1}{y+1}, \quad 0 \leq \mathcal{E}_m \leq \frac{2t^{2m+1}}{(2m+1)(1-t^2)}. \quad (53)$$

The same formula encloses $\log 2$; reciprocation handles $x < 1$. Finite rational LDL or principal-minor checks certify (47). No floating-point eigenvalue is accepted as proof of that inequality.

For actual analytic matrix enclosures, a sufficient input is $K_i^- \preceq K_i$ and $K_j \preceq K_j^+$ together with $K_i^- \succeq g_0 K_j^+$. Then (47) follows by transitivity. The trace moments in (49) also need certified input enclosures, or exact arithmetic; they are not automatically exact because a gap was enclosed. Independently,

$$\mathcal{L}_{i,j} \leq \log \det K_j^+ - \log \det K_i^- \quad (54)$$

when both bounding matrices are positive definite. The implemented test fixtures have exact rational entries. This note supplies no interval certificate for the actual arithmetic integrals or root coordinates.

S30.8 8. The off-line alternative forces a precise restriction phenomenon

For the packet consisting exactly of a quartet with displacement $\delta > 0$, height $\gamma > 0$, and common multiplicity m , retain

$$q_k = [1 + k(m-1)](k+1)^2. \quad (55)$$

The inherited endpoint theorem and its proved norm input give

$$\mathcal{B}_{h,k} \geq 2q_k \operatorname{arsinh} \left(\frac{\delta k}{2C_h} \right). \quad (56)$$

There are $2q_k$ positive eigenvalues g_a across the two return maps in (36). Equations (34) and (56) imply that at least one satisfies (6): otherwise every $-\log g_a$ would be smaller than the common lower average in (56), contradicting their sum.

An eigenvector v for that g_a is nonzero in the original arithmetic module. Equation (24) and the actual Gram calculation give

$$\boxed{\frac{\|P_{i,j} R_j v\|_{\mathcal{O}_j}^2}{\|R_j v\|_{\mathcal{O}_j}^2} = g_a, \quad \frac{\|(I - P_{i,j}) R_j v\|_{\mathcal{O}_j}^2}{\|R_j v\|_{\mathcal{O}_j}^2} = 1 - g_a.} \quad (57)$$

The old portion has arithmetic coordinate $g_a v$, not v . The exact original representative of v at degree i is recovered by applying $T_{i,j}^{-1}$ in (24). The difference from the full degree- j representative is the actual relation (30). Thus no arithmetic class is called absent, and no numerical near-zero is set equal to e .

The exact distributional statement is stronger than one selected direction:

$$\sum_{a=0}^1 \int_0^\infty \#\{b : g_b^{(a)} < e^{-s}\} ds = \mathcal{B}_{h,k}. \quad (58)$$

The growing-degree task can now be stated as control of this cumulative small-restriction spectrum, or as the positive trace certificates (51). A proved upper limit below 2 for $\mathcal{B}_{h,k}/(q_k \log k)$ would contradict (56). Such a uniform upper bound is not an output of the present finite identities.

S30.9 9. Exact calibration retaining nilpotence and mass

Use the explicitly declared algebraic fixture

$$E = \mathbb{C}[S]/((S-1)^2), \quad S = 1 + ix, \quad (59)$$

with the Gaussian source $7e^{-x^2/2}dx/\sqrt{2\pi}$, of literal mass seven and variance one. This fixture is not asserted to be a zeta packet. Its source monic polynomials and norms are

$$p_0 = 1, \quad p_1 = S - 1, \quad p_{n+1} = (S-1)p_n + np_{n-1}, \quad \omega_n = 7n!. \quad (60)$$

The coordinate basis $(1, S-1)$ is connected to $(1, S)$ by

$$C = \begin{pmatrix} 1 & -1 \\ 0 & 1 \end{pmatrix}, \quad (1, S)C = (1, S - 1). \quad (61)$$

In the $(1, S - 1)$ coordinates, the kernel matrices are

$$\begin{aligned} K_1 &= \text{diag}(1/7, 1/7), & K_2 &= \text{diag}(3/14, 1/7), \\ K_3 &= \text{diag}(3/14, 5/14), & K_4 &= \text{diag}(15/56, 5/14). \end{aligned} \quad (62)$$

The action remains $A = I + N$ with $N \neq 0$ and $N^2 = 0$. It is not replaced by its reduced one-dimensional quotient.

The two return spectra are exactly

$$\text{Spec } T_{1,3} = \{2/3, 2/5\}, \quad \text{Spec } T_{2,4} = \{4/5, 2/5\}. \quad (63)$$

Consequently

$$\mathcal{B} = \log(15/4) + \log(25/8) = \log(375/32) \approx 2.46119012317068427. \quad (64)$$

For $H_{1,3}$ the first two trace moments are $14/15$ and $106/225$; for $H_{2,4}$ they are $4/5$ and $2/5$. Using $g_0 = 2/5$ and $p = 2$ in (49) gives the two rigorously enclosed upper bounds whose displayed decimals are

$$1.32854908781965490, \quad 1.14133853675838303. \quad (65)$$

Their sum is below 2.469887624578038 . The earlier direct bound by $\text{Tr}(K_i^{-1}(K_j - K_i))$ gives $2 + 7/4 = 3.75$ on these two windows. Thus the new finite certificate makes a strict, verified improvement on the same source and same metrics. The exact logarithmic enclosures, rather than the printed rounded values, certify the comparison.

The dependent subset $\{0, 2\}$ in (37) has a supported zero minor because $[p_2] = [p_0]$ in this quotient. Nevertheless the first derivative coordinate at $S = 1$ is retained and makes the quotient dimension two. A distinct-root replacement would not give the same matrices.

The test suite also contains off-line algebraic fixtures, nonconstant invertible jet units, and repeated confluent derivatives. It does not infer a zeta-zero statement from these fixtures.

S30.10 10. Integration with the Deligne-oriented programme

The same cohomological transition now carries an explicit positive adjoint and a determinant-line norm. Its action covariance is (27), its theta-boundary correction is (30), and its original support quotient is retained in (32). This is a metric calculation on the existing characteristic-zero realization over b_+ .

Deligne's use of determinant weights and the compact-to-ordinary image requires an actual estimate on the same image. This note supplies additional calculation and finite upper certificates for that estimate; it does not invoke his finite-field purity hypotheses for the theta object. The inherited source review's strict inequality in Lemma 3.2.10 and its squared-eigenvalue step in 3.2.13 are retained. This turn did not newly reassemble the Deligne archive or claim a complete rereading.

Current repository input was checked at main 7ea0a49945390eae14d3160a5730858899768b5f. The current endpoint criterion retains the corrected top-exterior case and the actual second-exterior multiplicity cost. No second cost-free exterior amplification is used here. The proof status of the original norm bound (5) remains the inherited written analytic status; the present finite tests do not promote it to a Lean certificate.

The principal next quantity is no longer only an unnamed ratio of large determinants. It is the explicit log-loss of the original identity transports, with the canonical representative restriction, all original relations, full jets, arithmetic action, and complementary polynomial degrees attached. The uniform bound still needed is precisely the one on that constructed family.

Two-moment control of the original arithmetic relation blocks

S31.0.1 1. Result and the current inherited theorem

This note continues the canonical endpoint-restriction construction. It does not choose a different positive metric or replace the arithmetic source by a comparison measure. Its new application is an upper bound for each original relation-block volume from two source-derived traces, together with a complete positive remainder and a source interpretation of the second trace as exterior area.

The general sharp determinant optimization with prescribed dimension, trace, and squared trace is classical; Grone, Johnson, Marques de Sá, and Wolkowicz (1984) study precisely that optimization. The proof below is included in full, using a scalar Hermite interpolation identity. No priority claim is made for the general inequality. The work here is its composition with the actual arithmetic representative, internal quotient, inverse restriction, exterior source maps, and consecutive-window theorem.

For one original block, the output is

$$\frac{V_i}{V_j} \leq (1 + a_{i,j})(1 + b_{i,j})^{q-1}. \quad (1)$$

Both $a_{i,j}$ and $b_{i,j}$ are calculated from the first two traces of a specified endomorphism. There is no assumption that the arithmetic action is normal, no assumption that a restriction eigenspace is invariant under it, and no independently supplied lower gap for the restriction.

Integration of the two new reports The attachment reporting PR #25 supplies the phase-retaining consecutive product, the separate first-admissible-degree step, a two-sided written arithmetic norm envelope, and its comparable-window consequence. Its resulting off-line-quartet lower budgets are

$$\log(V_q/V_{2q}) \geq 2q \log(D_h k), \quad \log(V_{q-1}/V_{2q-1}) \geq 2q \log(D_h k), \quad (2)$$

for a fixed positive D_h , hence the four-volume lower threshold is **four**, not merely the earlier sufficient lower threshold two. This is inherited from the parallel contributions, not claimed as a discovery of this note. The source explicitly distinguishes its checked finite implications from the written analytic estimates and the asymptotic conclusion.

Its regularity clarification is retained: the actual arithmetic density is in $L^1 \cap L^\infty$, and

$$\|(\tau_a w_h - w_h) * w_h\|_\infty \leq \|\tau_a w_h - w_h\|_1 \|w_h\|_\infty \longrightarrow 0.$$

Here τ_a denotes translation of a function, not the split scalar τ ; its definition is $(\tau_a f)(t) = f(t - a)$. This supplies continuity of the convolution used in the source's lower-envelope argument.

The second attachment is a working transcript reporting further Gamma, coefficient-error, endpoint, and reflected-algebra work. Its reported moment certificates and unpublished upper-bound details are not independently reproduced here or silently made premises. In particular, this note does not duplicate its claimed fixed-budget extremizer or claim to have executed its local Windows commands.

GitHub main was read at 952ef9fee1e1419b6858d920354de8fa99430b7d. PR #25 was read at its reported verified head 66fac5e7885a40cd4873e74b754907320f05b067, including its full RESEARCH_NOT E.md. Its CI status is a source report; this session did not execute Lean.

S31.0.2 2. Original arithmetic source and support

Retain the original scalar object and amplitude map

$$G(R) = \{\tau\} \sqcup \{r^\bullet : r \in R\}, \quad e_R = 0_R^\bullet, \quad p_R(\tau) = 0_R, \quad p_R(r^\bullet) = r.$$

The original coefficient square remains

$$\begin{array}{ccc} G(\mathbb{Z}) & \xrightarrow{G(j)} & G(\mathbb{C}) \\ p_{\mathbb{Z}} \downarrow & & \downarrow p_{\mathbb{C}} \\ \mathbb{Z} & \xrightarrow{j} & \mathbb{C}. \end{array} \quad (3)$$

Its arithmetic target $\mathbb{Z}$ is infinite. The geometric base remains $\mathfrak{b}_\tau$. The square does not replace the internal support fibres by the ordinary amplitude observation.

Keep the original theta complex and generator

$$C_+ = [V \xrightarrow{\Theta} \mathcal{B}], \quad Q = \mathcal{B}/\Theta V, \quad D = -x\partial_x, \quad g = 2\xi.$$

For a nonempty full packet h of actual zeros and tensor degree k , retain the cyclic module and its action

$$E = \mathbb{C}[S]/(\chi_{h,k}), \quad q = \deg \chi_{h,k}, \quad A = M_S, \quad S = s_1 + \cdots + s_k.$$

The source and arithmetic inclusion are the constructed maps

$$\mathcal{V}P = P(D_1 + \cdots + D_k)(F_h^{\otimes k}), \quad \mathcal{M}F_h = g/h,$$

$$\eta[P] = v_h^{\otimes k} P(A_k) 1, \quad v_h = j_h(g/h), \quad (4)$$

$$J^{(k)}\mathcal{V} = \eta\pi_\chi, \quad q^{(k)}\mathcal{V} = \sigma_h^{\otimes k} \eta\pi_\chi.$$

The original norm is the integral against $m_{h,k} = w_h^{*k}$ on $S = k/2 + iu$, where

$$w_h(t) = \frac{|(g/h)(1/2 + it)|^2}{2\pi}, \quad \int m_{h,k} = \mu_h^k.$$

No mass is assigned a new value. All nilpotent jet orders and the unit in (4) remain in the arithmetic maps.

For $h = 1$ the finite packet is the zero coefficient module. Its determinant is the empty determinant one, its log-volume is zero, and $G(0)$ still contains the two split elements. The analytic theta seed remains nonzero. Positive-dimensional formulas below use $q \geq 1$; the divisions by $q - 1$ use $q \geq 2$.

Fixed polynomial coordinates Let $p_0, p_1, \dots$ be the original monic orthogonal polynomials and $\omega_n > 0$ their actual squared norms. Keep $\omega_0 = \mu_h^k$. In fixed remainder coordinates on E , set

$$b_n = [p_n]_\chi, \quad B_N = [b_0, \dots, b_N], \quad O_N = \text{diag}(\omega_0, \dots, \omega_N).$$

For every admitted $N \geq q - 1$,

$$K_N = B_N O_N^{-1} B_N^*, \quad G_N = K_N^{-1}, \quad R_N = O_N^{-1} B_N^* G_N, \quad V_N = \det G_N. \quad (5)$$

Thus $B_N R_N = I$ and $R_N^* O_N R_N = G_N$. The actual test-function representative is obtained by the specified polynomial-column realization $\mathcal{V}$, not by treating a coefficient vector as a function without that map.

S31.0.3 3. The positive cost operator comes from the original restriction

Fix $q - 1 \leq i \leq j$. Set $r = j - i$ and retain the new columns and their norms

$$F = F_{i,j} = [b_{i+1}, \dots, b_j] : \mathbb{C}^r \rightarrow E, \quad \Omega = \text{diag}(\omega_{i+1}, \dots, \omega_j),$$

$$D_{i,j} = K_j - K_i = F \Omega^{-1} F^*. \quad (6)$$

The Hilbert spaces $E_i = (E, G_i)$ and $E_j = (E, G_j)$ are connected by the actual forward transport $I_{i,j} : E_i \rightarrow E_j$, identity on the fixed coefficient space. Its adjoint is

$$T_{i,j} = I_{i,j}^\dagger = K_i G_j : E_j \rightarrow E_i.$$

To form an endomorphism of one specified Hilbert object, compose first:

$$Q_{i,j} = T_{i,j} I_{i,j} : E_i \rightarrow E_i.$$

The coefficient matrix of $Q_{i,j}$ is $K_i G_j$. Define

$$Z_{i,j} = Q_{i,j}^{-1} - I_E = (K_j - K_i) G_i = D_{i,j} G_i. \quad (7)$$

It is positive self-adjoint on E_i , because

$$G_i Z_{i,j} = G_i D_{i,j} G_i \succeq 0.$$

Its eigenvalues λ_a are nonnegative. The restriction eigenvalues in the preceding note are precisely

$$g_a = \frac{1}{1 + \lambda_a}, \quad \frac{V_i}{V_j} = \det(I_E + Z_{i,j}), \quad \log(V_i/V_j) = \sum_{a=1}^q \log(1 + \lambda_a). \quad (8)$$

No inverse-square-root transformation changes the canonical arithmetic metric. Equation (7) is a typed inverse of the already-constructed restriction endomorphism.

Source and action maps remain attached The source map $F : (\mathbb{C}^r, \Omega) \rightarrow (E, G_i)$ has adjoint

$$F^\dagger = \Omega^{-1} F^* G_i, \quad Z_{i,j} = F F^\dagger. \quad (9)$$

Let $H_N = G_N^{-1}(A^* G_N + G_N A - k G_N)$ be the inherited control endomorphism. Put $\hat{H}_j = I_{i,j}^{-1} H_j I_{i,j}$ on E_i . The previous action defect and inversion give

$$[A, Z_{i,j}] = \hat{H}_j (I + Z_{i,j}) - (I + Z_{i,j}) H_i. \quad (10)$$

Indeed $[A, Q] = H_i Q - Q \hat{H}_j$ and $[A, Q^{-1}] = -Q^{-1} [A, Q] Q^{-1}$. This is the actual relation between the cost operator and the arithmetic generator. A cost eigenspace is not presumed invariant for A .

S31.0.4 4. The two input traces are norms of actual source maps

Write

$$t_1 = \text{Tr } Z_{i,j}, \quad t_2 = \text{Tr}(Z_{i,j}^2), \quad \mathcal{A}_2 = \frac{t_1^2 - t_2}{2}. \quad (11)$$

The scalar $\mathcal{A}_2$ is the second exterior coefficient of this cost operator. Its split observation is $\mathcal{A}_2^\bullet \in G(\mathbb{R})$; a vanishing value maps to the represented scalar e .

From (6) and cyclicity of the finite trace,

$$t_1 = \sum_{n=i+1}^j \frac{b_n^* G_i b_n}{\omega_n},$$

$$t_2 = \sum_{n,m=i+1}^j \frac{|b_n^* G_i b_m|^2}{\omega_n \omega_m}, \quad (12)$$

$$\mathcal{A}_2 = \sum_{i < n < m \leq j} \frac{(b_n^* G_i b_n)(b_m^* G_i b_m) - |b_n^* G_i b_m|^2}{\omega_n \omega_m}. \quad (13)$$

The off-diagonal pairings in (12)–(13) are essential.

Let $\Phi = R_i F$ with its actual degree- i source norm. Then $t_1 = \|\Phi\|_{\text{HS}}^2$. Equip unscaled exterior bases with determinant Grams. The precise second identity is

$$\mathcal{A}_2 = \left\| \bigwedge^2 \Phi \right\|_{\text{HS}}^2. \quad (14)$$

Proof: in the coordinate wedge indexed by $n < m$, the squared source norm is $\omega_n \omega_m$. Its image squared norm is the two-by-two Gram determinant in (13). Summing proves (14). An alternating-tensor realization instead has its literal factor $2!$ in each wedge Gram; this statement uses the specified exterior quotient, so no factorial is dropped.

Let T_{new} denote the actual newly admitted orthogonal polynomial columns in the degree- j source. The source relation is

$$\mathbf{b}_{i,j} = T_{\text{new}} - L_{i,j} R_i F, \quad B_j \mathbf{b}_{i,j} = 0,$$

$$\mathbf{b}_{i,j}^* O_j \mathbf{b}_{i,j} = \Omega + F^* G_i F. \quad (15)$$

Thus (12)–(14) measure the old representative components needed to cancel the new columns' jets. The relation itself maps to the receiving supported zero through the original coequalizer. Neither component is declared absent.

An admitted pair with dependent images has zero exterior area in (13), a represented zero. The pair and its original support label remain available. A pair outside the degree-indexing object is absent. No statement that these two cases have the same upstream datum is used.

S31.0.5 5. A sharp two-trace upper bound, with a complete proof

Suppose $q \geq 2$. Define

$$d = \sqrt{\frac{qt_2 - t_1^2}{q-1}}, \quad a = \frac{t_1 + (q-1)d}{q}, \quad b = \frac{t_1 - d}{q}. \quad (16)$$

Both discriminants and signs come from the actual positive spectrum:

$$\begin{aligned} \frac{t_1^2}{q} &\leq t_2 \leq t_1^2, & 0 &\leq b \leq a, \\ a + (q-1)b &= t_1, & a^2 + (q-1)b^2 &= t_2. \end{aligned} \quad (17)$$

The spectral cap is proved, not supplied For any eigenvalue x of Z , Cauchy–Schwarz on the other $q-1$ eigenvalues gives

$$t_2 \geq x^2 + \frac{(t_1 - x)^2}{q-1}.$$

Solving this quadratic yields $x \leq a$. Hence the same two traces also produce the actual restriction-gap bound

$$Q_{i,j} \succeq \frac{1}{1+a} I_E \quad \text{in the original metric } G_i. \quad (18)$$

This is a finite derived bound, not a uniform estimate in k .

The optimal determinant bound from these two traces The result is

$$\log \det(I + Z) \leq U_2(Z) := \log(1+a) + (q-1) \log(1+b). \quad (19)$$

For $a > b$, define the quadratic

$$P_{a,b}(x) = \log(1+b) + \frac{x-b}{1+b} + c_{a,b}(x-b)^2,$$

$$c_{a,b} = \frac{\log(1+a) - \log(1+b) - (a-b)/(1+b)}{(a-b)^2} < 0. \quad (20)$$

It matches $\log(1+x)$ and its derivative at b , and the value at a . For $0 \leq x \leq a$ the exact remainder is

$$P_{a,b}(x) - \log(1+x) = (a-x)(x-b)^2 \int_1^\infty \frac{ds}{(s+x)(s+b)^2(s+a)} \geq 0. \quad (21)$$

Proof of (21): use $\log(1+x) = \int_1^\infty (1/s - 1/(s+x)) ds$ and the exact third divided difference of $1/(s+x)$. Interpolation at the repeated point b and at a gives the displayed rational denominator. The integral converges as s^{-4} ; all factors have their shown positive signs. This also directly proves the Hermite remainder without an unspecified intermediate point.

Sum (21) over the actual eigenvalues. Since a quadratic trace depends only on q, t_1, t_2 , equations (17) give

$$\text{Tr } P_{a,b}(Z) = P_{a,b}(a) + (q-1)P_{a,b}(b) = U_2(Z).$$

This proves (19) and (1).

If $a = b$, equality in $qt_2 \geq t_1^2$ forces every eigenvalue to equal b , so (19) is equality without the quotient in (20). If $q = 1$, the exact answer is $\log(1+t_1)$. If $t_1 = 0$, positivity gives $Z = 0$ and the volume is zero. If $q = 0$, use the empty determinant, without forming (16).

For $a > b$, the integrand in (21) is strictly positive except at $x = a, b$. Equality in (19) therefore holds exactly when the spectrum consists of one a and $q-1$ copies of b . These values have the original two traces by (17), so the bound is best possible given only those traces and the dimension. This does not assert that every such extremizer arises from an arithmetic packet.

The general optimization is classical. The source application uses precisely $Z = (K_j - K_i)G_i$, not an independently chosen Hermitian matrix.

S31.0.6 6. Retain the complete remainder; a third trace improves the bound

Let

$$C_3 = \text{Tr}((aI - Z)(Z - bI)^2) = -t_3 + (a+2b)t_2 - (2ab + b^2)t_1 + qab^2,$$

where $t_3 = \text{Tr } Z^3$. Positivity on the spectrum proves $C_3 \geq 0$.

The full loss in the upper bound is

$$U_2(Z) - \log \det(I + Z) = \int_1^\infty \frac{\text{Tr}((aI - Z)(Z - bI)^2(sI + Z)^{-1})}{(s + b)^2(s + a)} ds. \quad (22)$$

All four operator factors commute because they are functions of this same G_i -self-adjoint Z . The expression is positive in that same metric. No claim about commutation with A replaces (10).

Since $0 \leq x, b \leq a$, the integrand denominator in (21) is at most $(s + a)^4$. Therefore

$$\log \det(I + Z) \leq U_2(Z) - \frac{C_3}{3(1 + a)^3}. \quad (23)$$

This retains a concrete part of the higher-spectrum correction. It requires one further trace of the same source cost, not a new spectral gap or arithmetic realization.

Equation (19) is always at least as sharp as the trace-only bound

$$U_2(Z) \leq q \log(1 + t_1/q), \quad (24)$$

by scalar concavity and (17). Equality in (24), apart from a zero-dimensional case, requires $a = b$. It is not asserted to dominate every higher-moment certificate from the previous note; those can be retained and their certified upper bounds compared.

S31.0.7 7. The simplest bound exposes independent pair growth

For $q \geq 2$ and $t_1 > 0$, (17) implies

$$\mathcal{A}_2 = (q - 1)b \left(t_1 - \frac{q}{2}b \right).$$

Because $0 \leq b \leq t_1/q$,

$$\frac{\mathcal{A}_2}{(q - 1)t_1} \leq b \leq \frac{2\mathcal{A}_2}{(q - 1)t_1}, \quad a \leq t_1.$$

Consequently there is a radical-free finite upper bound

$$\frac{V_i}{V_j} \leq (1 + t_1) \left(1 + \frac{2\mathcal{A}_2}{(q - 1)t_1} \right)^{q-1}. \quad (25)$$

The quantity $\mathcal{A}_2$ is exactly the sum of the original two-column exterior areas (13), including every cross-pairing. The first trace alone cannot distinguish nearly parallel old representative corrections from many independent ones; (13) does make that distinction quantitatively.

If $\mathcal{A}_2 = 0$ and $t_1 > 0$, the positive operator has rank one, and the sharper formula (19) is the exact value $\log(1 + t_1)$. This is a statement about the rank of this specified comparison map, not a claim about uniqueness of the original scalar support or about the number of higher support fibres.

S31.0.8 8. Compose with the new consecutive-window theorem

The inherited phase-retaining product implies for every original admitted window $i, \dots, j - 1$, $r = j - i$, including $i = q - 1$ through its separately proved first-degree step,

$$\min_{i \leq N < j} \epsilon_N \leq \left(\frac{\omega_j}{\omega_i} \right)^{1/(2r)} \left(\frac{V_i}{V_j} \right)^{1/(2r)}. \quad (26)$$

This is credited to PR #25 and its source continuation. It uses the original norm and volume sequence. It does not require constructing an inverse before the first admissible degree.

Combining (1) and (26) proves the finite upper certificate

$$\min_{i \leq N < j} \epsilon_N \leq \left(\frac{\omega_j}{\omega_i} \right)^{1/(2r)} \left((1+a)(1+b)^{q-1} \right)^{1/(2r)}. \quad (27)$$

For either quartet block $(i, j) = (q, 2q)$ or $(q-1, 2q-1)$, the reviewed comparable-window norm bound supplies an inherited constant C_h^{win} independent of k . Enlarge it once to account for $i = q-1$. Then

$$\min_{i \leq N < j} \epsilon_N \leq C_h^{\text{win}} q(1+a)^{1/(2q)} (1+b)^{(q-1)/(2q)}. \quad (28)$$

The selected member is still a canonical degree in the original window. Its source relation, arithmetic unit, and action are not chosen again after selecting the degree.

Quantitative consequence of the already established off-line lower bound For the packet consisting exactly of an off-line quartet with full common multiplicity, retain

$$q_k = [1 + k(m-1)](k+1)^2, \quad L_{h,k} \geq \delta k q_k / 2.$$

Let $D_h > 0$ be the fixed constant in the inherited per-block lower inequality (2). The new upper bound implies, on each original block,

$$(D_h k)^{2q} \leq (1+a)(1+b)^{q-1}. \quad (29)$$

In the source area quantities it implies

$$\frac{2\mathcal{A}_2}{(q-1)t_1} \geq \left(\frac{(D_h k)^{2q}}{1+t_1} \right)^{1/(q-1)} - 1, \quad (30)$$

whenever that hypothetical lower budget is positive, so $t_1 > 0$. When the right side is negative the inequality remains valid but has no positive force.

This strengthens the earlier statement that the mean relation cost must grow: unless the total cost has an extremely large individual scale, there must also be substantial *two-direction exterior area* in the original correction map. It is not a lower bound on every correction eigenvalue.

For example, along such a family, a proved estimate $\log(1+t_1) = o(q \log k)$ would turn (30) into the necessary lower exponent

$$\liminf \frac{\log(1 + 2\mathcal{A}_2/((q-1)t_1))}{\log k} \geq 2.$$

This last statement is a consequence with that displayed premise, not a claimed arithmetic estimate. The actual unresolved calculation is to bound the explicit sums (12)–(13) along the required growing-degree quartet family. Their uniform size has not been established in this note.

For the two-block total, (19) yields

$$\mathcal{B}_{h,k} \leq U_2(Z^{(0)}) + U_2(Z^{(1)}).$$

The inherited lower threshold remains four. No new purity conclusion is inferred from finite positivity or the optimality of a generic determinant inequality.

S31.0.9 9. A finite certificate robust to moment enclosures

The sharp formula (16) uses exact traces. One must not insert uncertified decimal traces into it and call the result an upper certificate.

There is a direct error-aware alternative. Suppose proved enclosures give $t_1 \in [t_1^-, t_1^+]$ and $t_2 \in [t_2^-, t_2^+]$. A rational cap $A_0 \geq t_1^+$ bounds every nonnegative eigenvalue. Choose a rational $0 \leq B_0 < A_0$ and use the explicit polynomial P_{A_0, B_0} in (20).

The same positive remainder proves

$$\log \det(I + Z) \leq q \log(1 + B_0) + \frac{t_1 - qB_0}{1 + B_0} + c_{A_0, B_0}(t_2 - 2B_0 t_1 + qB_0^2). \quad (31)$$

Every coefficient in (31) is a rational combination of two logarithms of positive rationals. Rational interval arithmetic, including all products, gives a valid upper enclosure from the two trace intervals. It needs no separately certified bound $K_i \geq g_0 K_j$.

The checker encloses $\log x$ by writing $x = 2^e y$, $1 \leq y < 2$, and retaining both factors in

$$\log y = 2 \sum_{n=0}^{M-1} \frac{z^{2n+1}}{2n+1} + R_M, \quad z = \frac{y-1}{y+1}, \quad 0 \leq R_M \leq \frac{2z^{2M+1}}{(2M+1)(1-z^2)}.$$

The same formula encloses $\log 2$; reciprocation handles $x < 1$. These finite interval checks certify their supplied rational data only. An arithmetic application must supply certified moment/jet enclosures and hence valid trace intervals.

Arithmetic input size remains explicit For a direct construction through degree j , the source monic coefficients and norms are determined by the original convolution moments through degree $2j$, and the quotient columns retain the full coefficients of χ and the specified arithmetic inclusion. The sums (12)–(13) use G_i ; they do not require a second inverse G_j or an independent spectral-gap proof. This is not a claim that the required source moments are low-order or uniformly bounded. In the two length- q endpoint blocks, this direct route can require moments through $4q$. The parallel session's separate lower-input upper-volume comparison is not being replaced or credited as proved here.

Coordinate and mass propagation Under a fixed invertible quotient-coordinate map C , the actual data become

$$F \mapsto CF, \quad G_i \mapsto C^{-*} G_i C^{-1}, \quad Z \mapsto CZC^{-1}.$$

Thus both traces, $\mathcal{A}_2$, and the bound remain unchanged through that similarity. Raw confluent derivative coordinates keep their factorials in C ; the map is not silently made unitary.

A common source mass multiplier $c > 0$ gives

$$\Omega \mapsto c\Omega, \quad K_N \mapsto c^{-1} K_N, \quad G_N \mapsto cG_N,$$

so $Z, t_1, t_2, \mathcal{A}_2$ are unchanged by these displayed composites. The original mass has not been reset. An ambient rectangular arithmetic inclusion η is retained as an injection, not used as an invertible square coordinate map.

S31.0.10 10. Exact source calibrations

These are declared Gaussian polynomial fixtures, not asserted zeta packets. Use original coordinate $S = 1 + ix$, literal Gaussian mass seven, variance one, and quotient $\chi = (S - 1)^q$. The monic source recurrence and norms are

$$p_0 = 1, \quad p_1 = S - 1, \quad p_{n+1} = (S - 1)p_n + np_{n-1}, \quad \omega_n = 7n!.$$

All quotient matrices below are computed in the original remainder basis $1, S, \dots, S^{q-1}$.

For $q = 2$, the blocks (1, 3) and (2, 4) give

$$(t_1, t_2) = \left(2, \frac{5}{2}\right), \quad (t_1, t_2) = \left(\frac{7}{4}, \frac{37}{16}\right).$$

Their exact two-trace factors are $(a, b) = (3/2, 1/2)$ and $(3/2, 1/4)$, so

$$\frac{V_1}{V_3} = \frac{15}{4}, \quad \frac{V_2}{V_4} = \frac{25}{8}, \quad B = \log(375/32).$$

The two-moment upper bound is exact in dimension two. This matches the preceding restriction example without supplying a spectral gap.

For $q = 3$, the original block $(3, 6)$ has

$$t_1 = 11, \quad t_2 = \frac{3365}{32}, \quad \mathcal{A}_2 = \frac{507}{64}, \quad \frac{V_3}{V_6} = \frac{5145}{256},$$

$$a = \frac{11}{3} + \frac{7\sqrt{127}}{12}, \quad b = \frac{11}{3} - \frac{7\sqrt{127}}{24}.$$

Numerical evaluations of these exact expressions are

$$\log(V_3/V_6) \approx 3.000603203789, \quad U_2 \approx 3.063328308618, \quad 3 \log(1 + t_1/3) \approx 4.621335122841.$$

The exact checks use rational enclosures and polynomial identities, not these decimals as proof. The original operator has its full nonzero nilpotent jets. No inference from a restriction eigenvalue to an off-line arithmetic zero is made.

S31.0.11 11. What is established and what is handed onward

Established here are the source cost map (7)–(10), the first and second exterior source norms (12)–(15), the sharp two-trace upper bound with a proved cap (16)–(21), its positive remainder and third-trace refinement, the area-only upper certificate, and their composition with the current first-degree-correct consecutive theorem. These are written finite theorems; exact algebraic regression checks support their implementation. They are not additional Lean certificates.

The same canonical arithmetic volume is now bounded without a separate restriction-gap premise. Estimating the growing arithmetic values of (12)–(13) remains a real analytic task. This note does not assert a uniform bound completing RH, does not erase a non-radical packet, and does not turn an e -valued quotient observation into absence.

No remote branch, publication cut, or formalization source was changed. The handoff lists bounded reusable targets for the parallel session and leaves its own interval-moment and fixed-budget work untouched.

A flat rank- q deformation, its exact operator connection, and the logarithmic image of the preceding comparison curve

Source metadata: title (MetaInlines)

Deligne's exponential-family step and the original arithmetic packet

S32.0.1 1. What is new, and what the source actually supplies

This continuation reads further into Deligne's *La conjecture de Weil II*, especially §§3.7.2–3.7.4, while completing the cohomological calculation of the preceding representative curve. There are two new applications, with different roles.

First, the logarithmic de Rham complex of that curve is calculated, rather than inferred from its underlying coherent bundle. Its arithmetic coefficients occur in degrees zero and two; its degree-one middle image is zero. This identifies it as a constant-coefficient comparison curve, not as a nonconstant constituent in Deligne's pencil argument. The full coefficients and the source-induced metric are retained by explicit maps.

Second, an actual polynomial-exponential family is built from the existing cyclic relation polynomial. Its characteristic-zero cohomology is a free module of exactly the original packet rank, including at repeated roots. Its special fibre is the original cyclic quotient, and the original sum operator is the exact polar coefficient of its parameter connection. Its finite-field realizations have precisely the form to which Deligne applies his exponential-sum theorem. The two realizations are exhibited as base changes of the same polynomial data, not declared isomorphic and not assigned the same operator.

The new algebraic statements below have proofs. The finite-field purity statement is an application of Deligne's theorem under the hypotheses verified in Section 9. No arithmetic norm comparison between these exponential periods and the original theta metric is proved here. In particular, the finite-field Frobenius has not been identified with the original sum operator.

S32.0.2 2. Reading Deligne, rather than using the word purity

The supplied S20 archive was reassembled in this turn. All six binary parts were checked against their declared lengths and SHA-256 hashes. The resulting archive has 216,580,466 bytes, 312 members, and SHA-256 e2005bf31e1fcf362765f73c315c855e0f504f24f34d3a0ab188049da522b7c8.

The retained French and English LaTeX were read at the selected passages recorded in SOURCE_REVIEW.md, alongside the current page-local French records. No PDF extraction or OCR was used. The historical TeX is retained as a witness, not automatically treated as an error-free edition.

On printed pages 202–203, Deligne's argument has three separate inputs: the exceptional-fibre exact sequence, the integer weights of nonconstant constituents, and the independent bound strictly below two. Constant constituents have zero first cohomology on the projective line. The tensor-square step then improves the bound on the same Frobenius eigenvalue. On page 206, compact-support and ordinary-cohomology bounds meet on the image of their actual comparison.

The additional reading is printed pages 215–216. For a degree- d polynomial with d prime to the

residue characteristic and nonsingular leading projective hypersurface, Deligne proves concentration of the exponential-sheaf cohomology in degree n , dimension $(d-1)^n$, and weight n . His next step is to put the polynomials into a parameter space, prove lissity by local acyclicity including at infinity, and use connectedness and the weight results to reduce to a particular polynomial. The purity propagation used in that argument is explicitly stated on page 178, Corollary 1.8.12: on a connected base, a lisse mixed sheaf pure at one point is pointwise pure. Its proof passes through the filtration into pure constituents, rather than inferring purity merely from constant rank. This supplies an actual geometric family to build from our relation polynomial. The supplied reference for the final monomial case has an internal numbering mismatch, recorded in SOURCE_REVIEW.md; the displayed exponential theorem is used with its stated scope, not represented as a newly verified entire historical proof.

The source does not say that the critical points of a polynomial have real part one half. The operator singled out by its purity theorem is finite-field Frobenius. The connection coefficient calculated below is a different output of the same potential data, linked through the displayed realization diagram rather than an assumed equality.

S32.0.3 3. Original data and their supported realization

Retain the scalar construction and its specified maps:

$$G(R) = \{\tau\} \sqcup \{r^\bullet : r \in R\}, \quad e_R = 0_R^\bullet, \quad p_R(\tau) = 0_R, \quad p_R(r^\bullet) = r. \quad (1)$$

The original coefficient square remains

$$\begin{array}{ccc} G(\mathbb{Z}) & \xrightarrow{G(j)} & G(\mathbb{C}) \\ p_{\mathbb{Z}} \downarrow & & \downarrow p_{\mathbb{C}} \\ \mathbb{Z} & \xrightarrow{j} & \mathbb{C}. \end{array} \quad (2)$$

The first target is infinite. Every lifted scalar specialization below fixes external absence and sends a represented scalar zero to the represented zero of the receiving ring.

Keep the original theta complex, source function, full packet, and sum coordinate:

$$C_+ = [V \xrightarrow{\Theta} \mathcal{B}], \quad Q = \mathcal{B}/\Theta V, \quad D = -x\partial_x, \quad g = 2\xi, \quad h(s) = \prod_{\rho} (s - \rho)^{m_{\rho}}. \quad (3)$$

At tensor degree k , write

$$E = \mathbb{C}[S]/(\chi), \quad \chi = \chi_{h,k}, \quad q = \deg \chi > 0, \quad A = M_S, \quad (4)$$

where $S = s_1 + \cdots + s_k$, not its average. The existing cyclic inclusion is

$$\eta : E \hookrightarrow E_h^{\otimes k}, \quad \eta[P] = v_h^{\otimes k} P(A_k) 1, \quad v_h = j_h(g/h). \quad (5)$$

Its characteristic polynomial as a cyclic sum module need not be the characteristic polynomial of the entire tensor module. The actual injection (5), the previously constructed equivariant retraction, and its complementary module retain that distinction.

For an admitted degree N , retain the original canonical representative R_N and the source map $\mathcal{V}$:

$$J^{(k)} \mathcal{V} R_N = \eta, \quad q^{(k)} \mathcal{V} R_N = \sigma_h^{\otimes k} \eta, \quad R_N^* O_N R_N = G_N. \quad (6)$$

The monic norms in O_N have their original mass $\omega_0 = \mu_h^k$. No metric is chosen in this note to make an operator unitary. The empty-packet case has $E = 0$ and is handled outside all formulas requiring q positive.

S32.0.4 4. First compute the logarithmic cohomology of the preceding curve

For an original degree pair $i \leq j$, retain

$$\Delta = L_{ij} R_i - R_j, \quad C = \Delta^* O_j \Delta = G_i - G_j, \quad R(z) = R_j + z\Delta, \quad G(z) = G_j + |z|^2 C. \quad (7)$$

The predecessor constructs the image lattice on $X = \mathbb{P}_{\mathbb{C}}^1$, with boundary $D_{\infty} = \{\infty\}$ and $w = 1/z$:

$$\mathcal{M}_{E_0} = E_0\mathcal{O} + wE\mathcal{O}, \quad E_0 = \ker \Delta. \quad (8)$$

Its smallest A-stable enlargement is $\mathcal{M}_F = F\mathcal{O} + wE\mathcal{O}$, where

$$F = E_0 + AE_0 + \cdots + A^{q-1}E_0. \quad (9)$$

All statements below concern this original target E. Let $Q_F = E/F$ denote this finite quotient, not the theta quotient Q.

4.1 The actual differential

For any positive integer m, define the lattice

$$\mathcal{M}_{F,m} = F\mathcal{O} + \mathcal{O}(-mD_{\infty})E \subset E\mathcal{O}, \quad (10)$$

and its two-term logarithmic complex, in degrees zero and one,

$$\mathcal{K}_{F,m} = [\mathcal{M}_{F,m} \xrightarrow{d} \mathcal{M}_{F,m} \otimes \Omega_X^1(\log D_{\infty})]. \quad (11)$$

The differential is the restriction of the constant coefficient connection: in the local frame w^me its coefficient is $w\partial_w + m$. Consequently it preserves (10) after tensoring with logarithmic forms. Because F is A-stable, A acts on the entire complex. A choice of complement $E = F \oplus J$ gives the coefficient description $\mathcal{M}_{F,m} = F\mathcal{O} \oplus J\mathcal{O}(-m)$; the action can have an off-diagonal block and is not asserted to split with that choice.

Computed cohomology. The canonical identifications as A-modules are

$$\boxed{\mathbb{H}^0(X, \mathcal{K}_{F,m}) = F, \quad \mathbb{H}^1(X, \mathcal{K}_{F,m}) = 0, \quad \mathbb{H}^2(X, \mathcal{K}_{F,m}) = Q_F.} \quad (12)$$

Here is a direct calculation retaining the coefficients. For the compactly supported component, use the two affine charts and the finite frame at z. The Cech groups are

$$H^1(\mathcal{O}(-mD_{\infty})) = \text{span}\{z^{-1}, \dots, z^{-(m-1)}\},$$

$$H^1(\mathcal{O}(-mD_{\infty}) \otimes \Omega^1(\log D_{\infty})) = \text{span}\{z^{-1}dz, \dots, z^{-m}dz\}.$$

The induced differential is exactly

$$z^{-a} \mapsto -a z^{-(a+1)}dz, \quad 1 \leq a < m. \quad (13)$$

It is injective, and its cokernel is the line generated by $z^{-1}dz$. For the ordinary logarithmic component the complex is $[\mathcal{O} \rightarrow \mathcal{O}(-1)]$, with only the constant H^0 . The exact sequence of complexes with subobject F and quotient Q_F then gives (12) canonically, without an A-invariant complement. In particular the degree-two identification is residue in the displayed coordinate.

If the original arithmetic cochain degree k is restored by the shift $[-k]$, the coefficient groups are in degrees k and k+2. For every polynomial f,

$$\boxed{\text{Str}(f(A) \mid R\Gamma\mathcal{K}_{F,m}[-k]) = (-1)^k (\text{Tr } f(A|F) + \text{Tr } f(\bar{A}|Q_F)) = (-1)^k \text{Tr } f(A|E).} \quad (14)$$

The quotient retains all induced Jordan data. This is trace additivity on the original exact sequence, not deletion of its second term.

4.2 Compact, middle, and ordinary comparisons

Put

$$\mathcal{K}_! = [E\mathcal{O}(-D_{\infty}) \rightarrow E\Omega_X^1], \quad \mathcal{K}_{\text{mid}} = [E\mathcal{O} \rightarrow E\Omega_X^1], \quad \mathcal{K}_* = [E\mathcal{O} \rightarrow E\Omega_X^1(\log D_{\infty})]. \quad (15)$$

Their natural inclusions compute the usual compact-support, smooth middle, and ordinary comparisons for the constant coefficient system on $\mathbb{A}^1$. At m=1 the mixed complex fits $\mathcal{K}_! \rightarrow \mathcal{K}_{F,1} \rightarrow \mathcal{K}_*$. The cohomology groups are

$$H^a(\mathcal{K}_!) = \begin{cases} E & a = 2, \\ 0 & a \neq 2, \end{cases} \quad H^a(\mathcal{K}_*) = \begin{cases} E & a = 0, \\ 0 & a \neq 0, \end{cases} \quad (16)$$

and $\mathcal{K}_{\text{mid}}$ has E in degrees zero and two. In particular,

$$\boxed{\text{im}(H_c^1(\mathbb{A}^1, E) \rightarrow H^1(\mathbb{A}^1, E)) = 0.} \quad (17)$$

This is an application of Deligne's constant-constituent test to the actual constructed curve. It locates its role: it is a metric comparison with retained boundary data, not yet the nonconstant cohomological image carrying E in degree one. The constructive continuation to such a cohomological family begins in Section 5.

The two boundary comparisons remain explicit. For $m=1$, the termwise quotient $\mathcal{K}_*/\mathcal{K}_{F,1}$ is the punctual complex $[Q_F \xrightarrow{0} Q_F]$ in degrees zero and one, while $\mathcal{K}_{F,1}/\mathcal{K}_! = [F \xrightarrow{0} F]$. For general m the first quotient has local coefficient differential

$$w^a \mapsto aw^a dw/w, \quad 0 \leq a < m. \quad (18)$$

Every positive a is paired with its exact inverse coefficient $1/a$; the constant class survives in both degrees. Thus the extra coherent length is kept before its logarithmic differential is taken. In the split construction those cycles, boundaries, and their quotients use the original fibrewise operations. External absence is never used as the image of a represented boundary.

4.3 Ramification and saturation retain the metric cost The ramified parameter map $f_m : \mathbb{P}^1 \rightarrow \mathbb{P}^1$, $z \mapsto z^m$, gives the actual representative $R_m(z) = R_j + z^m \Delta$. Its pulled-back determinant curvature has radial density

$$\kappa_m(t) = m^2 t^{m-1} \text{Tr}(Z(I + t^m Z)^{-2}), \quad Z = G_j^{-1} C. \quad (19)$$

Substitution $v = t^m$ proves

$$\boxed{\int_0^\infty \kappa_m(t) dt = m \text{rank } C, \quad \int_0^1 \log(1/t) \kappa_m(t) dt = \log(V_i/V_j).} \quad (20)$$

The pullback on the surviving degree-two de Rham class is $dz/z \mapsto m dz/z$. It is not an identity disguised by dividing the trace by m .

In the A -stable enlargement, let $s_A = \dim F - \dim E_0$. Its determinant metric in the infinity chart is the old one multiplied by $|w|^{-2ms_A}$. With the retained curvature definition $(i/2\pi)\partial\bar{\partial} \log \det G$, the current is

$$\boxed{c_1((\det \mathcal{M}_{F,m})^\vee, h^\vee) = \mu_m - ms_A \delta_\infty.} \quad (21)$$

Indeed $(i/2\pi)\partial\bar{\partial} \log |w|^2 = \delta_\infty$. Its total mass is $m(q - \dim F)$, the degree of the dual determinant. Full saturation subtracts $m \text{rank } C$ at infinity and has total degree zero, but leaves the endpoint logarithmic integral (20) unchanged. The negative atom is a geometric current; it is not a negative support label.

S32.0.5 5. An actual rank- q cohomological deformation of the cyclic packet

Write the original monic polynomial in its original coordinate:

$$\chi(S) = S^q + \sum_{a=0}^{q-1} c_a S^a. \quad (22)$$

Introduce two new parameters u and t . They are independent of the scalar τ , the arithmetic coordinate S , the logarithmic comparison parameter z , and the tensor degree k . Put $R = \mathbb{C}[u, t]$ and define

$$\Phi(S) = \frac{S^{q+1}}{q+1} + \sum_{a=0}^{q-1} \frac{c_a S^{a+1}}{a+1}, \quad \Phi_t(S) = \Phi(S) - tS. \quad (23)$$

This is the specified primitive with $\Phi(0) = 0$, with every coefficient $1/(a+1)$ written. It changes no source coefficient in $g = 2\xi$. Define the two-term complex

$$\mathcal{C}_{u,t} = [R[S] \xrightarrow{\mathcal{D}_{u,t}} R[S]dS], \quad \mathcal{D}_{u,t}(P) = (uP'(S) + (\chi(S) - t)P(S))dS, \quad (24)$$

in degrees zero and one.

Flatness and exact rank. There is a direct sum of R-modules

$$R[S] = \mathcal{D}_{u,t}(R[S])/dS \oplus R[S]_{<q}. \quad (25)$$

In particular,

$$H^0(\mathcal{C}_{u,t}) = 0, \quad \mathcal{H} := H^1(\mathcal{C}_{u,t}) \cong R^q, \quad \mathcal{H}/(u,t)\mathcal{H} \cong E. \quad (26)$$

Proof. If P has degree a and leading coefficient b, then $uP' + (\chi - t)P$ has degree $a+q$ and leading coefficient b. It cannot be zero. For any polynomial F of degree at least q, subtract $\mathcal{D}_{u,t}(bS^{\deg F - q})/dS$ to remove exactly its highest term. Repeating terminates with a remainder of degree below q. Uniqueness follows from the leading-degree statement. The coefficients stay in R throughout. The same proof survives arbitrary base change of R, so (25) is a split exact presentation, not only a dimension count over its fraction field. Specializing $u=t=0$ turns (24) into multiplication by the literal χ , proving the final isomorphism.

Let $\text{red}_{u,t}$ denote the resulting coefficient-linear remainder map and $s_{<q}$ its specified polynomial section. The fibre map in (26) is $[P]_{\mathcal{D}} \mapsto [P|_{u=t=0}]_{\chi}$, with inverse induced by the chosen remainder basis.

There is no ring quotient asserted for u nonzero. Its exact relationship to multiplication is the commutator

$$[\mathcal{D}_{u,t}/dS, M_S] = uI. \quad (27)$$

For example, $\mathcal{D}(1)/dS = \chi - t$, while $\mathcal{D}(S)/dS = u + S(\chi - t)$; hence $[S(\chi - t)] = -u[1]$ in $\mathcal{H}$. The image of the differential is generally not an ideal. Formula (25) supplies the coefficient module and its section; the next paragraph supplies the operator that really descends.

S32.0.6 6. The parameter connection contains the original sum operator

On $\mathcal{H}[u^{-1}]$, define

$$\nabla_t[P] = [\partial_t P - SP/u]. \quad (28)$$

The exact relation

$$[\mathcal{D}_{u,t}/dS, \partial_t] = I, \quad [\mathcal{D}_{u,t}/dS, -M_S/u] = -I \quad (29)$$

proves that their sum commutes with the differential. Thus (28) descends without asserting that multiplication by S separately descends.

In the specified remainder basis $1, S, \dots, S^{q-1}$, the connection is

$$\nabla_t = \partial_t - \frac{A(t)}{u}, \quad A(t) = A + t\mathcal{R}, \quad \mathcal{R} = e_0 e_{q-1}^T. \quad (30)$$

Here $Ae_a = e_{a+1}$ for $a < q-1$ and

$$A(t)e_{q-1} = (-c_0 + t)e_0 - c_1 e_1 - \dots - c_{q-1} e_{q-1}. \quad (31)$$

Only a degree-q polynomial has to be reduced in deriving (30); $\mathcal{D}(1) = \chi - t$ gives exactly (31), including the sign of t.

The operator $-u\nabla_t = -u\partial_t + A(t)$ is regular in u and obeys the exact coefficient rule $(-u\nabla_t)(fv) = f(-u\nabla_t)v - u(\partial_t f)v$. It is a parameter-scaled connection in the t direction, not a derivative in u. Its reduction at $u=0$ is the honest endomorphism $A(t)$, and

$$\boxed{(-u\nabla_t) \bmod (u, t) = A = M_S \text{ on } E.} \quad (32)$$

This is the precise operator bridge. It contains a minus sign fixed by (24) and (28). The original arithmetic scaling is not renamed Frobenius.

Carry the parameter through the original theta representative Let $r_N = \mathcal{V}R_N : E \rightarrow \mathcal{B}^{\widehat{\otimes} k}$. On its specified test-function domain, use the earlier full jet map followed by the fixed equivariant cyclic retraction to obtain j_E with

$$j_E r_N = I_E, \quad j_E D^{(k)} = A j_E, \quad j_E \text{ kills the original theta boundaries.} \quad (33)$$

The construction of j_E uses the retained equivariant retraction, not an arbitrary quotient of the full tensor packet. Define the concrete finite-rank perturbation

$$\boxed{D_t^{(k)} = D^{(k)} + t r_N \mathcal{R} j_E.} \quad (34)$$

Then

$$j_E D_t^{(k)} = A(t) j_E, \quad \boxed{D_t^{(k)} r_N - r_N A(t) = D^{(k)} r_N - r_N A = dK_N.} \quad (35)$$

Both identities follow by substitution. The added term vanishes on every original boundary because j_E does. Thus the deformation has an explicit source realization preserving the original relation primitive. At $t=0$ it is exactly the original generator. At t nonzero it is the displayed finite-rank deformation, not a new assertion about the zero set of g .

The canonical arithmetic metric remains G_N . Its parameter control is explicitly

$$\boxed{W_N(t) = W_N(0) + t G_N \mathcal{R} + \bar{t} \mathcal{R}^* G_N.} \quad (36)$$

No positive metric has been selected from the exponential family to replace G_N .

6.1 The exponential periods are constructed and proved to span Fix a nonzero complex u , write $d=q+1$, and fix an argument of u . Set

$$\theta_0 = \frac{\arg u + \pi}{d}, \quad \theta_j = \theta_0 + \frac{2\pi j}{d} \quad (0 \leq j < d). \quad (36a)$$

Let ℓ_j be the oriented ray from zero to infinity with angle θ_j , and set $\Gamma_j = -\ell_0 + \ell_j$ for $1 \leq j \leq q$. The minus sign makes the initial endpoint contributions cancel. For a polynomial P define

$$\mathcal{P}_j(P) = \int_{\Gamma_j} e^{\Phi_t(S)/u} P(S) dS, \quad \Pi_{jb}(u, t) = \mathcal{P}_j(S^b), \quad 0 \leq b < q. \quad (36b)$$

These are absolutely convergent contour integrals. Along each ray the leading exponent is $-r^d/(d|u|)$. Lower-degree terms are dominated by that negative term outside a sufficiently large compact interval, uniformly when the lower coefficients and t range over a compact set. The same estimate after multiplying by any polynomial proves holomorphic dependence on those parameters and justifies their differentiation under the integral.

Integration of the actual total derivative gives

$$\mathcal{P}_j(uP' + (\chi - t)P) = u \int_{\Gamma_j} d(e^{\Phi_t/u} P) = 0. \quad (36c)$$

Both ends at infinity have zero boundary value, and the two values at zero cancel. Consequently the periods descend through the very differential (24), not through a quotient chosen afterwards.

The period matrix is invertible for every choice of the lower coefficients and every t , at this fixed nonzero u . Here is a direct proof, including the singular critical-point cases.

Temporarily regard the coefficients $c_0, \dots, c_{q-1}$ as independent parameters. The coefficient-direction connections are

$$\nabla_{c_a} = \partial_{c_a} + \frac{S^{a+1}}{(a+1)u}, \quad [\mathcal{D}/dS, \nabla_{c_a}] = 0. \quad (36d)$$

The two commutator terms are $-S^a$ and $+S^a$. Reducing $S^{a+b+1}/((a+1)u)$ by (25) gives the b-th column of a q-by-q matrix B_a . Every entry is a polynomial in the lower coefficients and t, with powers of the fixed u^{-1} . Thus

$$\partial_{c_a} \Pi = \Pi B_a, \quad \partial_t \Pi = -\Pi A(t)/u. \quad (36e)$$

At the monomial potential $\Phi = S^d/d$, $t=0$, direct substitution in the ray integral gives

$$\Pi_{jb}^{\text{mon}} = \frac{(d|u|)^{(b+1)/d}}{d} \Gamma\left(\frac{b+1}{d}\right) e^{i(b+1)\theta_0} \left(e^{2\pi i j(b+1)/d} - 1\right). \quad (36f)$$

All Gamma factors, all powers, and all phases remain. The final q-by-q matrix is nonsingular: a dependence among its columns would give a polynomial $\sum_{l=1}^q a_l(z^l - 1)$ of degree at most q vanishing at every d-th root of unity, including 1. It has $d=q+1$ distinct zeros, so it is the zero polynomial and every a_l vanishes.

For the phase matrix $V_{jl} = e^{2\pi i j l/d} - 1$, $1 \leq j, l < d$, finite root-of-unity summation also gives $V^*V = d(I_q + \mathbf{1}\mathbf{1}^T)$ and $\det(V^*V) = d^d$. This evaluates its nonzero size without absorbing any of the Gamma factors in (36f).

Join this monomial parameter to the actual parameter by a straight line in the coefficient space, keeping the rays fixed. Equations (36e) give $\Pi' = \Pi B$ with an everywhere continuous, explicitly reduced matrix B. Differentiation of the determinant, valid through the adjugate formula even at a putative singular matrix, yields

$$(\det \Pi)' = (\text{Tr } B) \det \Pi. \quad (36g)$$

Its initial value is nonzero by (36f). The scalar equation has solution given by that value times the exponential of the integral of $\text{Tr } B$, and never vanishes. This proves the stated invertibility without assuming simple critical points or a basis of unproved cycles.

It follows that the actual period map is the coefficient-linear isomorphism

$$\boxed{\mathcal{H}_{u,t} \xrightarrow{(\mathcal{P}_1, \dots, \mathcal{P}_q)} \mathbb{C}^q, \quad [P] \mapsto \Pi(u, t) \text{red}_{u,t}(P),} \quad (36h)$$

with inverse given by $\Pi(u, t)^{-1}$ followed by the specified degree-below-q section. Polynomial-exponential de Rham cohomology and rapid-decay period pairings are established machinery; (36a)–(36h) give an elementary proof of the particular one-variable comparison used here, with its contours and factors fixed.

6.2 Transport the period norm through the original source map Use the explicit coefficient identification

$$j_{u,t} : E \xrightarrow{\sim} \mathcal{H}_{u,t}, \quad [P]_{\chi} \mapsto [\text{rem}_{\chi} P]_{\mathcal{D}_{u,t}}. \quad (36i)$$

This is a complex-linear basis comparison. It is not a ring morphism when the target differential image is not an ideal. Equations (30)–(35) are the operator comparisons attached to it.

The original representative image now has an actual period isomorphism and inverse:

$$\boxed{r_N(E) \xrightarrow{\Pi(u,t)j_E} \mathbb{C}^q, \quad y \mapsto r_N \Pi(u, t)^{-1} y.} \quad (36j)$$

Their two composites are identities on the specified domains, by $j_E r_N = 1$. The same map applied to a retained theta boundary gives zero because j_E kills that boundary; its split lift gives the receiving supported zero, not external absence.

The operator comparison also holds at the level of actual period functions. For a t-independent F in the admitted theta test-function domain, (33), (35), and (36e) give

$$\boxed{-u \partial_t (\Pi(u, t) j_E F) = \Pi(u, t) j_E D_t^{(k)} F.} \quad (36j.1)$$

At $t=0$ the right side uses the original $D^{(k)}$. On the full test-function domain the kernel of this period observation is exactly $\ker j_E$, because Π is invertible. It remains an explicit retained kernel; the isomorphism (36j) concerns only the stated representative image $r_N(E)$.

Give the period-coordinate target its explicitly chosen ordinary coordinate Gram I_q and write

$$H_\Pi = \Pi^* \Pi, \quad B_N^{\text{per}} = G_N^{-1} H_\Pi. \quad (36k)$$

Then B_N^{per} is positive self-adjoint in the original G_N , and

$$\|\Pi v\|^2 = v^* G_N B_N^{\text{per}} v, \quad \boxed{\log \frac{V_i}{V_j} = \log \frac{\det B_j^{\text{per}}}{\det B_i^{\text{per}}}.} \quad (36l)$$

The latter follows from $\det B_N^{\text{per}} = \det H_\Pi / \det G_N$ at the same (u, t) . Thus the endpoint cost has been carried into two explicit period-to-source norm comparisons; it has not been set to zero by choosing period coordinates. The degree of the cyclic packet and the fixed contour-coordinate metric remain in the formula. Equation (36l) is a comparison identity, not a uniform bound on those determinants.

For $q=1$, $\chi(S) = S - \lambda$, real $u > 0$, and the contour $i\mathbb{R}$ oriented from $-i\infty$ to $+i\infty$, the integral is exactly

$$\boxed{\Pi(u, t) = i\sqrt{2\pi u} \exp\left(-\frac{(\lambda+t)^2}{2u}\right), \quad -u \partial_t \log \Pi = \lambda + t.} \quad (36m)$$

This uses the displayed orientation; it is the negative of the $q=1$ ray-difference cycle in (36a). The positive metric value for real λ, t is $2\pi u \exp(-(\lambda+t)^2/u)$. Its exponentially singular u -behaviour is retained. Thus even in rank one, passage through $u=0$ is a substantive norm-comparison question, not a consequence of finite-field purity of a different operator.

S32.0.7 7. A constant residue pairing gives the exact dual connection

On the remainder basis define the complex-bilinear form

$$\mathcal{S}_t(P, Q) = \sum_{\chi(\lambda)=t} \text{Res}_{S=\lambda} \frac{P(S)Q(S)}{\chi(S) - t} dS. \quad (37)$$

Multiplicity is handled by the residue, not by an assumption that the roots are simple. The form can equivalently be evaluated as the coefficient of S^{-1} in the Laurent expansion at infinity of the displayed rational function. This is minus the residue at infinity, so the sign agrees with the sum of the finite residues.

For degree-below- q P, Q ,

$$\boxed{\mathcal{S}_t(P, Q) = \mathcal{S}_0(P, Q).} \quad (38)$$

Indeed,

$$\frac{1}{\chi - t} - \frac{1}{\chi} = \frac{t}{\chi(\chi - t)},$$

and multiplication by PQ , whose degree is at most $2q - 2$, gives a Laurent expansion beginning at S^{-2} . Its S^{-1} coefficient is zero. Let S be the constant matrix. Its entries below the first nonzero antidiagonal vanish and that antidiagonal has entries one, so

$$\det S = (-1)^{q(q-1)/2}, \quad \boxed{A(t)^T S = S A(t).} \quad (39)$$

The latter equation follows because multiplication by S is self-adjoint for the residue pairing on the algebra $\mathbb{C}[S]/(\chi - t)$; (30) is precisely its multiplication matrix in this basis.

Let ι_u be the base involution $(u, t) \mapsto (-u, t)$. The actual dual map is

$$\boxed{\mathcal{H}[u^{-1}] \longrightarrow (\iota_u^* \mathcal{H}[u^{-1}])^\vee, \quad v \longmapsto (w \mapsto v^T S w).} \quad (40)$$

It is horizontal:

$$\partial_t(v^T S w) = (\nabla_t^u v)^T S w + v^T S (\nabla_t^{-u} w). \quad (41)$$

This is a bilinear duality; the original Hermitian arithmetic pairing is connected on the special fibre by its retained antilinear reflection $f \mapsto f^{\dagger k}$. In particular the Jacobian contraction is still

$$\boxed{\mathcal{S}_0(f^{\dagger k}, \chi' v) = \text{Tr}_E M_{f^{\dagger k} v}.} \quad (42)$$

The proof is the local equality $\chi'/\chi = \ell_\lambda/(S-\lambda) + \text{a holomorphic term}$. The trace on the full original tensor or symmetric packet is still obtained through η and its retained complement; (42) is not silently substituted for that larger trace. Likewise the original factor $v_h^{\otimes k}$ stays in (5) and (6).

S32.0.8 8. The split coefficient maps and the original derivative tower

The family is over $R = \mathbb{C}[u, t]$, with scalar map $G(\mathbb{C}) \rightarrow G(R)$. Its reconstruction at any original support label ℓ has classes (ℓ, v) , and

$$e_R(\ell, v) = (\ell, 0), \quad \tau(\ell, v) = \tau. \quad (43)$$

The specialization $R \rightarrow \mathbb{C}$, $u, t \mapsto 0$, lifts to a semiring map $G(R) \rightarrow G(\mathbb{C})$, fixing τ and carrying both $u^\bullet, t^\bullet$ to the receiving e . The induced coefficient map is

$$(\ell, [P]_{\mathcal{D}}) \longmapsto (\ell, [P(0, 0, S)]_{\chi}). \quad (44)$$

For every P , the exact family relation is

$$[\chi P] = t[P] - u[P'] \quad \text{in } \mathcal{H}. \quad (45)$$

At $u=t=0$, this becomes the original supported zero. This family identity must not be substituted for the already formalized derivative between powers of the original relation ideal. Their precise polynomial relationship is

$$\partial_S(\chi P) = \chi' P + \chi P', \quad [\partial_S(\chi P)]_{\chi} = [\chi' P]_{\chi}, \quad (46)$$

whereas the u -term of (45) contains $-P'$. Both are obtained from the same polynomial and the displayed maps. The conormal response $\chi' P$ remains exactly the Jacobian in (42). None of the new parameters is another scalar zero-adjunction, and no original ideal-power level is replaced by a power of a contracted first ideal.

S32.0.9 9. This potential has actual Deligne exponential-sheaf fibres

Let R_0 be the finitely generated subring of $\mathbb{C}$ generated by the coefficients c_a and $1/(q+1)!$. Keep its specified embedding into $\mathbb{C}$. Equations (23) and (24) are defined over $R_0[u, t]$.

For every specified ring map $R_0 \rightarrow \mathbb{F}_Q$ with residue characteristic $p > q+1$, and every $u_0 \in \mathbb{F}_Q^*$ and $t_0 \in \mathbb{F}_Q$, the same potential gives the explicit Artin-Schreier cover

$$\boxed{Y^p - Y = \frac{\Phi(S) - t_0 S}{u_0}.} \quad (47)$$

The infinity calculation in Deligne's lissity proof can be made explicitly on this family. Put $d = q+1$ and $w = 1/S$. Then

$$\frac{\Phi(S) - tS}{u} = w^{-d}b(w, u, t), \quad b(w, u, t) = \frac{1}{u} \left[\frac{1}{d} + \sum_{a=0}^{q-1} \frac{c_a}{a+1} w^{q-a} - tw^q \right]. \quad (47a)$$

At $w=0$ its value is the unit $1/(du)$. On the neighborhood where b is invertible, adjoin the unit v by $bv^d = 1$ and define $x_\infty = wv$. This is an explicit finite étale cover: the derivative in v is dbv^{d-1} , whose inverse on the cover is v/d . The new relative coordinate has invertible derivative at $w=0$. Direct substitution gives

$$\boxed{\frac{\Phi(S) - tS}{u} = x_\infty^{-d}, \quad x_\infty = wv, \quad bv^d = 1.} \quad (47b)$$

Every coefficient in b is retained, as is the cover's root-of-unity action $v \mapsto \zeta v, \zeta^d = 1$. This is the local, étale source map used to see a constant exponential model at infinity. Together with the locally constant sheaf on the smooth affine part, it is exactly the local-acyclicity mechanism used in Deligne's §3.7.3. The open u nonzero remains necessary; this map makes no claim at $u=0$.

Choose a nontrivial additive character $\psi : \mathbb{F}_p \rightarrow \overline{\mathbb{Q}}_\ell^*$, with $\ell \neq p$, and let $\mathcal{L}_\psi((\Phi - t_0S)/u_0)$ be the corresponding eigensheaf. The polynomial on the right has degree $q+1$, prime to p , and leading coefficient $1/((q+1)u_0)$. In one variable its leading projective zero locus in $\mathbb{P}^0$ is empty, and is smooth. Thus the precise hypotheses of Deligne §3.7.2 hold.

His theorem supplies

$$\boxed{H_c^a(\mathbb{A}_{\mathbb{F}_Q}^1, \mathcal{L}_\psi((\Phi - t_0S)/u_0)) = 0 \ (a \neq 1), \quad \dim H_c^1 = q, \quad H_c^1 \text{ is pure of weight } 1.} \quad (48)$$

The universal-polynomial argument in §§3.7.3–3.7.4 supplies a lisse family on the parameter open $u \neq 0$, after that finite-field specialization. This is a direct application of Deligne's result, not a new proof of it.

The exact realization diagram is a span of specified base changes:

$$(R_0, \Phi, u, t) \longrightarrow \left\{ \begin{array}{l} (\mathbb{C}, \mathcal{C}_{u,t}, \nabla_t), \\ (\mathbb{F}_Q, \mathcal{L}_\psi((\Phi - tS)/u), R^1p_!). \end{array} \right. \quad (49)$$

Its characteristic-zero branch has the proved specialization (26) and operator formula (32). Its finite-field branch has Frobenius and (48). No field map $\mathbb{C} \rightarrow \mathbb{F}_Q$ is asserted; both arrows start at the actual ring R_0 . Nor is a comparison equating the two operators supplied. The arithmetic theta metric G_N is not part of Deligne's finite-field conclusion until an additional comparison theorem carries it there.

This places the cyclic relation in a genuine family of the kind Deligne studies, instead of attributing his nonconstant-constituent argument to the constant representative curve. It leaves an explicit operator/norm comparison to investigate.

A calibration of the operator distinction Take the declared algebraic polynomial $\chi(S) = S - 3/4$; this is not an asserted zeta packet. Then

$$\Phi(S) = S^2/2 - 3S/4, \quad A(t) = 3/4 + t, \quad \nabla_t = \partial_t - (3/4 + t)/u. \quad (50)$$

All the rank, specialization, and duality results above hold. At every finite-field realization of characteristic greater than two where the coefficient is defined, (48) still gives weight-one Frobenius. The characteristic-zero special coefficient remains $3/4$. This exact example shows why a purity theorem for the displayed Artin-Schreier family does not, by itself, locate the spectrum of (32). The additional comparison must use the specific original arithmetic source, not only the fact that a polynomial-exponential realization exists.

S32.0.10 10. What this changes in the programme

The predecessor's nonconcentration problem remains

$$\mathcal{B}_{h,k} = \sum_{\ell=0}^1 \int_{|z|<1} \log(1/|z|^2) d\mu_\ell. \quad (51)$$

The reviewed source-norm theorem and consecutive-window result still force the inherited off-line threshold of four. Neither log extension, finite ramification, nor saturation changes its original endpoint metric cost; (20) and (21) state precisely how those operations act.

What is added is a cohomological family with the exact original cyclic special fibre, an explicit connection containing A , an explicit dual connection, and finite-field exponential fibres covered by a theorem actually read in Deligne. The source-side realization (34)–(36) specifies the finite-rank deformation and keeps the theta boundary. The contour periods now give actual isomorphisms at u nonzero and the matrices $B_N^{\text{per}} = G_N^{-1} \Pi^* \Pi$ give their exact comparison to the fixed arithmetic metric. Equation (36l) carries the endpoint volume into their determinant ratio. The remaining estimate must control those specified matrices through singular $u=0$ and along the original tensor/degree windows. The existence of the period isomorphism or of scalar support is not itself that uniform estimate.

This continuation proves no new upper bound contradicting the endpoint threshold. It does provide the actual family and the exact maps on which a Deligne-style comparison can be attempted, after calculating and retaining the limitations of the earlier constant curve.

S32.0.11 References and verification scope

Deligne, P. (1980), *La conjecture de Weil II*, Publications Mathématiques de l’IHÉS 52, 137–252. Selected current source records: printed pages 201–203, 206, 215–216, 248. Retained French and English TeX windows are listed in SOURCE_REVIEW.md.

The Stacks Project, Section 50.15, Tag 0FMU, *Log poles along a divisor*. Its residue exact sequence fixes the complexes in (15); the actual calculations in (12), (13), and (18) are given here. The comparison is made in complexes of complex vector-space sheaves, since their connections are coefficient-linear, not $\mathcal{O}_X$ -linear.

The new exact tests are finite regression checks of the displayed polynomial, matrix, quotient, connection, residue, and Čech formulas. They do not certify infinite arithmetic integrals, compile new Lean modules, or prove a realization comparison absent from this note. The frozen predecessor is preserved. No remote branch is modified by this delivery.

Marco Hien (2009), *Periods for flat algebraic connections*, Inventiones Mathematicae 178, 1–22, DOI 10.1007/s00222-009-0185-7, is primary background for de Rham/rapid-decay duality. Only its bibliographic record and abstract were consulted here; no general theorem from it is needed in the direct contour proof (36a)–(36h).

S33.1 Arithmetic norm review and comparable-degree windows

The owner supplied the 2026-09-13 arithmetic endpoint note. Its principal input is the actual density $w_h = |2\xi/h|^2/(2\pi)$, its k -fold convolution, and the unscaled monic squared norms $\omega_{h,k,j}$. This is a review and extension of that written proof, not a Lean certificate for zeta estimates or arithmetic integrals. The locally linked delivery archive was not accessible in this runtime; its reported test and manifest results are not counted as fresh executions.

S33.1.1 1. Audit of the analytic steps

The Joukowski ellipse with $|w|=8$ has semiaxes $65/16$ and $63/16$. For $f_T(z) = \zeta(1/2 + iT + iz)$, $|T| \geq 10$ keeps the pole outside its closure. Its image lies in the fixed real strip $[-55/16, 71/16]$, with imaginary magnitude between $|T| - 65/16$ and $|T| + 65/16$. Split that strip at $\operatorname{Re}(s) = 1/4$. Above this value, the fractional-part integral gives polynomial growth $O((1+|T|))$; below it the functional equation and vertical-strip gamma estimate give $O((1+|T|)^{(1/2 - \operatorname{Re}(s) + 1)})$. The largest exponent is $79/16 < 6$. Thus the claimed envelope $M_T = C_0(1+|T|)^6$ is sufficient, uniformly on the ellipse. Increase C_0 so $M_T \geq 1$.

The point $z = -3i/2$ corresponds to $|w| = (3 + \sqrt{13})/2 < 4$ and hence to $\zeta(2 + iT)$. The reciprocal Dirichlet series gives modulus at least $\zeta(2)^{-1}$. The annular maximum principle gives $m_T \geq \zeta(2)^{-3} M_T^{-2}$. Every closed unit disk centred on $[-1, 1]$ lies strictly within the ellipse: its surrounding rectangle $[-2, 2] \times [-1, 1]$ already satisfies the ellipse inequality. The maximum principle and Cauchy estimate therefore give $\sup |f_T| \leq M_T$. At a maximizer use the longer one-sided interval in $[-1, 1]$, of length at least one; $m_T/(2M_T) \leq 1/2$. Integration gives $m_T^3/(8M_T)$ and the stated exponent 42. The compact remaining T -range is handled by continuity and analytic nonvanishing on an interval. No nonvanishing on the critical line is assumed.

For the passage to $|g/h|$, use $g = h(g/h)$ before taking absolute values. The polynomial upper bound on $|h|$ avoids division at a selected zero. Gamma asymptotics yield the claimed interval-mass bound. One regularity detail should be explicit: w_h is bounded as well as integrable, by its continuous entire quotient on compact sets and exponential tail. Thus $w_h * w_h$ is continuous, using L^1 translation continuity against the bounded factor. Its integrand is positive almost everywhere, so the convolution is strictly positive everywhere. This justifies its positive minimum on $[-1, 1]$. Restricting the remaining factors to that interval proves the note's lower envelope with the original factor $\vartheta_h(k-3)$.

The monic Legendre norm on $[-L, L]$ is exactly

$$l_n(L) = 2 \frac{L^{2n+1}}{(2n+1)!} [2^n n! / (2n)!]^2.$$

The trial upper bound at degree j is $(2j)! b^{(-2j)} (M_h(b)^k + M_h(-b)^k)$, for fixed $0 < b < \pi/2$. Both are used on the original shifted line $S = k/2 + iu$; multiplication by i^j has modulus one and does not change the leading coefficient norm. These arguments validate the supplied $O_h(n)$ doubling-window result as a written theorem, not as a floating-point or Lean assertion.

S33.1.2 2. Stronger, two-sided envelope

Write $a = \pi/2$ and retain the lower-envelope constants $c > 0$, $\vartheta > 0$, $B = 42 + 2 \deg(h)$. Put

$$\begin{aligned} t &= \min(1, \vartheta), \quad c_0 = \min(1, 2c/3), \\ \text{ell} &= (1/2) \exp(-a) \sqrt{c_0 t} 2^{(-B/2)}, \\ M &= \max(1, M_h(b), M_h(-b)), \quad U = 4 \sqrt{M}/b. \end{aligned}$$

Then, for every $n \geq k \geq 3$,

$$(e11\ n)^{(2n)} \leq \omega_{(h,k,n)} \leq (U\ n)^{(2n)}. \quad (A)$$

Proof of the lower bound: $l_n(n) \geq (2/3)n^{(2n)4^{(-n)}}$; $\vartheta^{(k-3)} \geq t^n$; $\exp(-a(n+k-3)) \geq \exp(-2an)$; $(1+n+k-3)^{(-B)} \geq (2n)^{(-B)} \geq 2^{(-nB)}$, since $2n \leq 2^n$ for integer $n \geq 1$; finally $2c/3 \geq c0^n$. Multiply. For the upper bound use $(2n)! \leq (2n)^{(2n)}$, $k \leq n$ and $M_h(b)^k + M_h(-b)^k \leq 2M^n$, then $2 \leq 4^n$. This proves (A), retaining all masses in constants rather than resetting them.

For $n \geq k \geq 3$ and $n/2 \leq r \leq 2n$, let $m = n + r$. From (A),

$$\begin{aligned} & (\omega_m/\omega_n)^{(1/(2r))} \\ & \leq n\ U^{(1+n/r)}\ e11^{(-n/r)}(1+r/n)^{(1+n/r)} \\ & \leq C_h\ n, \\ C_h = & 27\ \max(1,U)^3\ \max(1,e11^{(-1)})^2. \end{aligned} \quad (B)$$

This extends the doubling-window estimate to the overlapping windows needed by the volume theorem. Constants depend only on the fixed h and chosen b , not k, n, r . No monotonicity of the monic norms is assumed. The inequality is valid at $r = n$ and at $r = n + 1$ when $n \geq 1$.

References: NIST DLMF 25.4 (functional equation), 5.11.9 (uniform bounded-real-part gamma asymptotic), 18.3 (Legendre normalization). The general arguments above are written proofs; the present Lean contribution formalizes their finite norm-to-volume consequences, not their analytic hypotheses.

S34.1 Consecutive losses and the arithmetic endpoint threshold

S34.1.1 Source, scope, and notation

This add-only continuation starts from main 7ea0a49945390eae14d3160a5730858899768b5f. The source is the owner's arithmetic endpoint note dated 2026-09-13 and the previously supplied exact Toda and exterior formulas. NORM_REVIEW.md audits its analytic proof and establishes the comparable-window extension used below. Those analytic results have written proofs, not a new Lean certificate. The Lean files prove the finite propagation independently of assuming RH, normality of the arithmetic action, or an estimate for the quotient volume.

Keep the original packet h , $g=2x_i$, theta source, full Taylor unit, canonical representatives R_N , and arithmetic cyclic module $C[S]/\chi(h,k)$. Write $q=\dim C$. The norms ω_N are the unscaled monic source norms; $V_N=\det G_N$ are its canonical quotient volumes. The phase is $\phi_N=\sigma\text{-partial_theta} \log V_N$. Λ_N below is ω_N/V_N , NOT the global theta retraction denoted Λ in earlier notes.

S34.1.2 1. Exact consecutive product

For $N \geq q$ the existing identity is

$$\begin{aligned} \epsilon_N^{2+\phi_N} &= (\omega_{N+1}/\omega_N)(1-\delta_N)(\delta_{N+1})^{(-1)-1}, \\ \delta_N &= V_N/V_{N-1} \text{ in } (0,1]. \end{aligned}$$

Rearrange it as

$$\begin{aligned} (\epsilon_N^{2+\phi_N}) \Lambda_N &= \Lambda_{N+1}(1-\delta_N)(1-\delta_{N+1}). \end{aligned} \quad (1)$$

For $n \geq q$ and $r \geq 1$, multiplication and cancellation of positive Λ -values gives

$$\begin{aligned} \text{product}_{(j < r)} (\epsilon_{n+j}^{2+\phi_{n+j}}) &= (\omega_{n+r} V_n) / (\omega_n V_{n+r}) \\ &\quad (1-\delta_n)(1-\delta_{n+r}) \\ &\quad \text{product}_{(0 < j < r)} (1-\delta_{n+j})^2. \end{aligned} \quad (2)$$

Every interior contraction occurs twice. This is an exact phase-retaining identity; the Lean theorem `exact_product` proves its general algebraic form. In particular,

$$\begin{aligned} \min_{(j < r)} \epsilon_{n+j} &\leq [(\omega_{n+r} V_n) / (\omega_n V_{n+r})]^{1/(2r)}. \end{aligned} \quad (3)$$

The finite minimum exists. Equation (3) follows by bounding each factor $1-\delta$ by one, comparing the product with the minimum's $2r$ -th power, and taking a nonnegative root. This proof does not require Jensen or the earlier four-endpoint hyperbolic-sine bound. It need not be sharper when contractions are small.

The local coarse bound $\epsilon_N^2 \Lambda_N \leq \Lambda_{N+1}$ also holds at $N=q-1$. Use the separate first-degree identity

$$\begin{aligned} \epsilon_{q-1}^{2+\phi_{q-1}} &= (\nu_\theta - \omega_q) / \omega_{q-1}, \\ V_q/V_{q-1} &= \omega_q/\nu_\theta. \end{aligned}$$

It follows that $\epsilon_{(q-1)}^2 \Lambda_{(q-1)} \leq \Lambda_q$. No inverse at degree $q-2$ is introduced. Thus (3) and the lower-allowance consequence below apply to windows starting at $q-1$, although the exact two-contraction identity (2) is used only from q onward.

S34.1.3 2. The actual spectral lower allowance forces each single block

The existing original-Gram exterior/trace theorem gives $L_{(h,k)} \leq \epsilon_N$ for every admitted N . Iterating the coarse local inequality proves

$$L_{(h,k)}^{(2r)} \Lambda_n \leq \Lambda_{(n+r)}. \quad (4)$$

If the actual norm bound gives $\omega_{(n+r)}/\omega_n \leq C^{(2r)}$, then

$$(L_{(h,k)}/C)^{(2r)} V_{(n+r)} \leq V_n. \quad (5)$$

For $L > 0, C > 0$ this is

$$\log(V_n/V_{(n+r)}) \geq 2r \log(L_{(h,k)}/C). \quad (6)$$

The formal propagation, norm comparison, and log conversion have separate declarations, so the analytic premise is explicit.

For the exact hypothetical quartet, retain

$$\begin{aligned} q_k &= [1+k(m-1)](k+1)^2, \\ L_{(h,k)} &\geq \delta * k * q_k / 2, \quad \delta > 0. \end{aligned}$$

By NORM_REVIEW.md, both windows $(n,r)=(q_k,q_k)$ and (q_{k-1},q_k) have norm factors at most $C_h q_k$. Indeed $q_{k-1} \geq k$ for $k \geq 3$, and r is between $n/2$ and $2n$. The first window uses only regular local degrees; the second begins at the separately checked first degree. Let $D_h = \delta / (2C_h) > 0$. Then

$$\begin{aligned} \log(V_{(q_k)}/V_{(2q_k)}) &\geq 2q_k \log(D_h k), \\ \log(V_{(q_{k-1})}/V_{(2q_{k-1})}) &\geq 2q_k \log(D_h k). \end{aligned} \quad (7)$$

Therefore the source's SAME four-volume budget satisfies the stronger implication

$$\begin{aligned} B_{(h,k)} &= \log[V_{(q_{k-1})}V_{(q_k)}/(V_{(2q_{k-1})}V_{(2q_k)})] \\ &\geq 4q_k \log(D_h k), \\ \liminf B_{(h,k)}/(q_k \log k) &\geq 4. \end{aligned} \quad (8)$$

The source's threshold 2 remains correct but is not optimal after retaining the adjacency of the exact radius equations. This is a new deduction, not a correction falsely attributed to its original proof. No upper estimate below 4 is claimed. Either one-block upper limsup below 2 would already suffice for contradiction, while a total upper limsup below 4 would also suffice. Multiplicities remain in q_k .

S34.1.4 3. Relation-layer meaning

For the original block (i,j) , put $F=[b_{(i+1)}, \dots, b_j]$, $\Omega = \text{diag}(\omega_{(i+1)}, \dots, \omega_j)$. The supplied map $b = T \cdot R_i F$ is an isomorphism onto $D_j \cap D_i^\perp$, with Gram $\Omega + F^* G_i F$, and original quotient value zero. Hence

$$V_i/V_j = \det(I + \Omega^{-1} F^* G_i F).$$

Take the positive generalized eigenvalues λ_a of $(F^* G_i F, \Omega)$. The two blocks $(q-1, 2q-1)$ and $(q, 2q)$ each have q source coordinates. Equations (7) imply, for each block separately,

$$\begin{aligned} \text{product}_a (a=1..q) (1+\lambda_a) &\geq (D_h k)^{(2q)}, \\ \text{geometric_mean}(1+\lambda_a) &\geq (D_h k)^2, \\ (1/q) \sum_a \lambda_a &\geq (D_h k)^2 - 1. \end{aligned} \quad (9)$$

The arithmetic-geometric mean inequality proves the last line. This does NOT force every λ_a to grow. Their multiplicity and rank profile remain. On the split lift the actual final quotient sends each retained relation to the receiving label's supported zero, not to external τ . Its source Gram is measured before that map.

S34.1.5 4. Constant and source accounting

No measure is normalized. The original mass $\omega_0 = \mu_h^k$ remains, and its effect is in the explicit constants of NORM_REVIEW.md. The Taylor multiplier and its derivative are not omitted. The norm leading-coefficient quotient is not identified with the arithmetic quotient. No complementary arithmetic block, nilpotent direction, or cochain sign is removed.

The analytic proof and the asymptotic consequence (8) are written mathematics. The new Lean run, when successful, certifies the finite local/product/forcing interfaces named in AuditConsecutiveWindow.lean; it does not certify the complex-analytic zeta argument, the arithmetic integrals, or a new weight theorem. Consult the PR for the exact completed run rather than treating this source note as an execution receipt.

S35 Complete supplied specialization and curvature continuation

Source role. Complete supplied mathematical text, retained with its original formulas and source chronology. The present integrated chapters state and prove the subsequent corrections and exact maps.

Exact revision. ed20dd4c189eb741d666edbaa964a03f616279a90e88b171bb9f31bba8652106

Complete source. sources/endpoint_user_sources/USER_SPECIALIZATION_CURVATURE_PROOF_20260913.txt

Source SHA-256. ed20dd4c189eb741d666edbaa964a03f616279a90e88b171bb9f31bba8652106

I added an actual compactification, specialization calculation, and dual boundary to the existing arithmetic representatives. The main result is that the endpoint volume we have been trying to control is exactly a logarithmic curvature integral on that compactified curve:

$$\log \frac{V_i}{V_j} = \int_{|z|<1} \log \frac{1}{|z|^2} c_1((\det \mathcal{E}_{ij})^\vee).$$

The curve is constructed from the **original theta relation**

$$\Delta_{ij} = L_{ij}R_i - R_j.$$

Its exceptional fibre, the directions killed by specialization, and their duals are calculated. The previous two trace inputs become the first two curvature coefficients of this same object.

There is also an additional repair: when the original arithmetic action develops a pole at the exceptional fibre, I construct its **smallest action-stable enlargement** and calculate the metric contribution that enlargement retains.

[Full derivation in the HTML reader](#) · [LaTeX](#) · [Formalization handoff](#) · [Complete package](#)

S35.0.1 1. What the Deligne rereading adds

I reassembled and hash-checked the six supplied S20 parts, then read the relevant retained French and English LaTeX against the current page-local French records. The [reading record](#) identifies the exact files, ranges, and transcription discrepancies. This is a selected reading of *La conjecture de Weil II*, not a new audit of its entire proof. ([Numdam](#))

The decisive addition is **not just another tensor operation**.

In §§3.2.8–3.2.13, Deligne first controls what occurs at the exceptional fibres. The resulting calculation gives integral weights for the relevant nonconstant constituents. The independent bound is **strictly below two**, so those integral weights are at most one. Constant constituents contribute zero to the specified first cohomology of the projective line. Only after those steps do the Leray and tensor-square maps improve the bound on the same eigenvalue.

The older French transcription loses two essential details: it writes a non-strict inequality in 3.2.10 and loses the square on the tensor eigenvalue in 3.2.13. The current page record retains both.

The later purity statement also concerns a particular comparison:

$$H_c^i(X, \mathcal{F}) \twoheadrightarrow \text{im } c_i \hookrightarrow H^i(X, \mathcal{F}).$$

The two already-proved bounds meet on that image; the mixed source and target are not removed. The degree and dualizing twist are part of the argument.

What I added here is the corresponding concrete work on our side: construct the curve, calculate the exceptional comparison and its complete fibre, retain the action, and calculate the determinant metric on that object.

S35.0.2 2. Build the curve from the existing representatives

Keep the original coefficient square over the marked τ -base:

$$\begin{array}{ccc} G(\mathbb{Z}) & \xrightarrow{G(j)} & G(\mathbb{C}) \\ p\mathbb{Z} \downarrow & & \downarrow p\mathbb{C} \\ \mathbb{Z} & \xrightarrow{j} & \mathbb{C}. \end{array}$$

The first arithmetic target remains infinite. The split coefficients retain $e = 0^\bullet$ and external absence τ before applying p .

For the current finite cyclic object,

$$E = \mathbb{C}[S]/(\chi_{h,k}), \quad A = M_S,$$

retain

$$K_N = B_N O_N^{-1} B_N^*, \quad G_N = K_N^{-1}, \quad R_N = O_N^{-1} B_N^* G_N.$$

Here B_N is the original full remainder matrix, O_N contains the actual monic source norms, and the arithmetic inclusion still contains $v_h^{\otimes k}$. The canonical metric is determined by that source and its admitted relations.

For $i \leq j$, pad the earlier source through

$$L_{ij} : \mathcal{P}_i \hookrightarrow \mathcal{P}_j$$

and define

$$\Delta = L_{ij} R_i - R_j : E \longrightarrow \mathcal{P}_j.$$

Both representatives have remainder identity, and the later representative is orthogonal to its relation space. Therefore

$$B_j \Delta = 0, \quad R_j^* O_j \Delta = 0,$$

and

$$C := \Delta^* O_j \Delta = G_i - G_j \succeq 0.$$

Now form the actual family

$$R(z) = R_j + z\Delta : E \longrightarrow \mathcal{P}_j.$$

Direct expansion gives

$$B_j R(z) = I_E, \quad G(z) := R(z)^* O_j R(z) = G_j + |z|^2 C.$$

Every finite z therefore retains the same arithmetic jets and cohomology class:

$$J^{(k)} \mathcal{V} R(z) = \eta, \quad q^{(k)} \mathcal{V} R(z) = \sigma_h^{\otimes k} \eta.$$

The marked endpoints are

$$R(0) = R_j, \quad R(1) = L_{ij} R_i.$$

The new coordinate z parametrizes this comparison. The original spectral coordinate remains S , with its original action A .

S35.0.3 3. Compactify it and compute the exceptional fibre

Set

$$E_0 = \ker \Delta, \quad E_1 = E_0^{\perp G_j}, \quad r = \dim E_1.$$

Let P_0, P_1 be the corresponding specified projections.

On $\mathbb{P}_{\mathbb{C}}^1$, with homogeneous coordinates $[u : v]$, define

$$\mathcal{E}_{ij} = (E_0 \otimes \mathcal{O}) \oplus (E_1 \otimes \mathcal{O}(-1)).$$

The map into the original source is

$$\begin{aligned} \Psi : \mathcal{E}_{ij} &\longrightarrow \mathcal{P}_j \otimes \mathcal{O}, \\ x_0 + x_1 \otimes (u, v) &\longmapsto R_j x_0 + u R_j x_1 + v \Delta x_1. \end{aligned}$$

This is injective on every fibre. For $u \neq 0$, applying B_j forces $x_0 = x_1 = 0$. At $u = 0$, it first forces $x_0 = 0$, and injectivity of $\Delta|_{E_1}$ forces $x_1 = 0$.

On the finite chart $z = v/u$, this is exactly $R(z)$. On the infinity chart $w = u/v$, it is

$$\Psi_{\infty}(w) = R_j P_0 + w R_j P_1 + \Delta P_1.$$

The original arithmetic observation becomes

$$\alpha = B_j \Psi : \mathcal{E}_{ij} \longrightarrow E \otimes \mathcal{O},$$

with local expression

$$\alpha_{\infty} = P_0 + w P_1.$$

Consequently,

$$0 \longrightarrow \mathcal{E}_{ij} \xrightarrow{\alpha} E \otimes \mathcal{O} \longrightarrow i_{\infty*} E_1 \longrightarrow 0.$$

This is the effective-divisor exact sequence on the modified columns, with its actual source map supplied above. ([The Stacks Project](#))

The lost fibre is retained in the derived comparison Specializing $w = 0$ gives P_0 . The derived fibre of the displayed cokernel is the actual complex

$$[E \xrightarrow{P_0} E] \quad \text{in degrees } -1, 0.$$

Its cohomology is

$$H^{-1} = E_1, \quad H^0 = E_1.$$

Intrinsically, the kernel carries

$$E_1 \otimes \mathcal{O}(-1)|_{\infty};$$

the chosen infinity frame gives the displayed coefficient identification.

In the split lift,

$$w^{\bullet} \longmapsto e$$

under specialization. A represented vector killed by P_0 maps to the receiving supported zero, **and remains present in the derived kernel**. External absence maps to τ . This is precisely the original internal-homology treatment of a class whose image becomes a boundary.

The global comparison is also calculated:

$$\boxed{H^0(\mathbb{P}^1, \mathcal{E}_{ij}) = E_0, \quad H^1(\mathbb{P}^1, \mathcal{E}_{ij}) = 0.}$$

Its source image is $E_0 \subseteq E$. The full E remains the target and the saturation of the image lattice; it is not silently assigned to the smaller global image.

S35.0.4 4. Duality and the arithmetic action now have explicit boundary maps

Dualizing the comparison gives

$$\boxed{0 \rightarrow E^* \otimes \mathcal{O} \rightarrow \mathcal{E}_{ij}^\vee \rightarrow i_{\infty*}(E_1^* \otimes \mathcal{O}(1)|_\infty) \rightarrow 0.}$$

The two boundary factors pair through

$$\boxed{(E_1 \otimes \mathcal{O}(-1)|_\infty) \otimes (E_1^* \otimes \mathcal{O}(1)|_\infty) \longrightarrow \mathbb{C}_\infty.}$$

Both line factors remain.

The connection transported through α is

$$\nabla_\infty = d + P_1 \frac{dw}{w}.$$

Its residue is P_1 , and its horizontal monodromy is

$$\exp(-2\pi i P_1) = I.$$

The original arithmetic operator transports through the same map:

$$\boxed{\hat{A}_\infty = (P_0 + w^{-1}P_1)A(P_0 + wP_1) = \begin{pmatrix} A_{00} & wA_{01} \\ w^{-1}A_{10} & A_{11} \end{pmatrix}.$$

Thus the precise possible pole is

$$w^{-1}P_1AP_0.$$

The kernel of a metric comparison has not been presumed A -invariant.

Construct the smallest enlargement that repairs that pole Take the actual invariant hull

$$\boxed{F_A = E_0 + AE_0 + \cdots + A^{q-1}E_0, \quad q = \dim E.}$$

Cayley–Hamilton proves that this is the smallest A -invariant subspace containing E_0 .

Let $\mathcal{M} = \alpha(\mathcal{E}_{ij})$. At infinity,

$$\mathcal{M}_\infty = E_0\mathcal{O} + wE\mathcal{O}.$$

Its smallest coherent A -stable enlargement inside the original target is

$$\boxed{\mathcal{M}_A = \sum_{a=0}^{q-1} A^a \mathcal{M}, \quad (\mathcal{M}_A)_\infty = F_A\mathcal{O} + wE\mathcal{O}.$$

The exact sequences are

$$0 \rightarrow \mathcal{M} \rightarrow \mathcal{M}_A \rightarrow i_{\infty*}(F_A/E_0) \rightarrow 0,$$

and

$$0 \rightarrow \mathcal{M}_A \rightarrow E \otimes \mathcal{O} \rightarrow i_{\infty*}(E/F_A) \rightarrow 0.$$

The second sequence now carries the regular original action throughout. It gives the equivariant global sequence

$$0 \rightarrow F_A \rightarrow E \rightarrow E/F_A \rightarrow 0$$

and retains the trace

$$\mathrm{Tr} f(A) = \mathrm{Tr}(f(A)|F_A) + \mathrm{Tr}(f(\bar{A})|E/F_A).$$

The enlargement has a calculated source cost. Put

$$s_A = \dim F_A - \dim E_0.$$

The inclusion of the old lattice into the enlarged one has determinant w^{s_A} . Pulling through the **original** source metric gives

$$\det G_A(w) = |w|^{-2s_A} \det G_{\mathcal{M}}(w).$$

Regularizing the arithmetic action transfers the retained boundary contribution into a specified metric pole. It does not make that contribution disappear.

S35.0.5 5. The endpoint cost is the determinant curvature of this curve

Let

$$\mathcal{L}_{ij} = (\det \mathcal{E}_{ij})^\vee.$$

Its metric in the finite chart is

$$(\det G(z))^{-1}.$$

Define the curvature with its complete coefficient:

$$c_1(\mathcal{L}_{ij}) = \frac{i}{2\pi} \partial \bar{\partial} \log \det G(z).$$

The operator in this formula is exactly the preceding relation-cost operator:

$$Z = G_j^{-1}(G_i - G_j) = (K_j - K_i)G_i.$$

It is positive self-adjoint for G_j .

Differentiation gives

$$c_1(\mathcal{L}_{ij}) = \frac{i}{2\pi} \mathrm{Tr} [Z(I + |z|^2 Z)^{-2}] dz \wedge d\bar{z}.$$

Write

$$\kappa_{ij}(t) = \mathrm{Tr} [Z(I + tZ)^{-2}].$$

The coordinate identity

$$i \, dz \wedge d\bar{z} = 2 \, dx \wedge dy$$

and polar integration give

$$\int_{\mathbb{P}^1(\mathbb{C})} c_1(\mathcal{L}_{ij}) = \int_0^\infty \kappa_{ij}(t) \, dt = r.$$

That agrees with the independently computed divisor:

$$\det \alpha = u^r, \quad \deg \mathcal{L}_{ij} = r.$$

Recover the exact endpoint volume Put

$$f(t) = \log \det(I + tZ), \quad M(t) = t f'(t).$$

Then

$$M'(t) = \kappa_{ij}(t), \quad M(0) = 0.$$

Fubini gives

$$\begin{aligned} \int_0^1 \log(1/t) \kappa_{ij}(t) \, dt &= \int_0^1 \frac{1}{s} \int_0^s \kappa_{ij}(t) \, dt \, ds \\ &= \int_0^1 f'(s) \, ds \\ &= \log \det(I + Z). \end{aligned}$$

Since $G(1) = G_i$ and $G(0) = G_j$,

$$\log \frac{V_i}{V_j} = \int_0^1 \log(1/t) \kappa_{ij}(t) \, dt.$$

This is the same endpoint ratio as before, now computed on a compactified, marked curve with its boundary sheaf and metric.

Its second fundamental map retains the arithmetic cancellation The actual source projection is

$$P_z = R(z)G(z)^{-1}R(z)^*O_j.$$

Define

$$\mathcal{N}_z = (I - P_z)\Delta.$$

Then

$$\mathcal{N}_z^* O_j \mathcal{N}_z = C - |z|^2 C G(z)^{-1} C,$$

and

$$\mathrm{Tr}[G(z)^{-1} \mathcal{N}_z^* O_j \mathcal{N}_z] = \kappa_{ij}(|z|^2).$$

The individual arithmetic observations are

$$B_j P_z \Delta = \bar{z} G(z)^{-1} C,$$

$$B_j \mathcal{N}_z = -\bar{z} G(z)^{-1} C.$$

Their sum is the original relation. **Neither projected part is declared a boundary separately.** Their cancellation is retained before its quotient value becomes e .

S35.0.6 6. The previous trace certificate is now a curvature-jet estimate

Differentiating the curvature density at the marked point gives

$$\kappa_{ij}^{(n)}(0) = (-1)^n (n+1)! \operatorname{Tr}(Z^{n+1}).$$

Therefore the last note's quantities satisfy

$$t_1 = \kappa_{ij}(0), \quad t_2 = -\frac{1}{2} \kappa'_{ij}(0).$$

Its independent-pair quantity becomes

$$\mathcal{A}_2 = \frac{1}{2} \left(\kappa_{ij}(0)^2 + \frac{1}{2} \kappa'_{ij}(0) \right).$$

Thus the already-proved two-trace bound is now a bound on the logarithmic curvature moment of this particular determinant line:

$$\int_{|z|<1} \log(1/|z|^2) c_1(\mathcal{L}_{ij}) \leq \log(1+a) + (q-1) \log(1+b).$$

The a, b on the right are precisely the earlier functions of q, t_1, t_2 . No new estimate is being attributed to Deligne here; the geometric object underlying our existing estimate has been constructed.

S35.0.7 7. The construction also follows the actual arithmetic constituents

Deligne's determinant-weight bookkeeping concerns constituents, so I carried this construction through an actual invariant inclusion

$$I_F : F \hookrightarrow E, \quad A I_F = I_F A_F.$$

Set

$$R_F(z) = R(z) I_F, \quad G_F(z) = I_F^* G(z) I_F, \quad \Delta_F = \Delta I_F.$$

The resulting constituent bundle maps into $\mathcal{E}_{ij}$. On its modified part, the map is explicitly

$$x \otimes (u, v) \longmapsto u P_0 I_F x + P_1 I_F x \otimes (u, v).$$

Its composite with Ψ is exactly the constituent source map, including at infinity.

The original control compresses through the same inclusion:

$$W_F(z) = I_F^* W(z) I_F = A_F^* G_F(z) + G_F(z) A_F - k G_F(z).$$

Its determinant action satisfies

$$2\Re \operatorname{Tr} A_F - k \dim F = \operatorname{Tr} [G_F(z)^{-1} W_F(z)].$$

The original theta primitive also varies explicitly:

$$K(z) = (1 - z)K_j + zK_i,$$

$$D^{(k)}\mathcal{V}R(z) - \mathcal{V}R(z)A = dK(z).$$

Consequently,

$$W(z) = W_j + |z|^2(W_i - W_j) = -[(\mathcal{V}R(z))^* dK(z) + (dK(z))^* \mathcal{V}R(z)].$$

This connects the constituent curve, its determinant metric, and its **actual spectral action**. The integer curve degree is not substituted for the trace on the left.

S35.0.8 8. What is now available for the remaining estimate

For the two original endpoint blocks, let their determinant-curvature measures be μ_0, μ_1 . Then

$$\mathcal{B}_{h,k} = \sum_{\ell=0}^1 \int_{|z|<1} \log(1/|z|^2) d\mu_\ell, \quad \int d\mu_\ell = r_\ell \leq q_k.$$

The inherited off-line-quartet implication remains

$$\liminf_{k \rightarrow \infty} \frac{\mathcal{B}_{h,k}}{q_k \log k} \geq 4.$$

I checked the pinned GitHub proof and retained its stated scope.

So the remaining upper estimate is now a **nonconcentration estimate for two specified source-induced curvature measures**, with their exceptional fibres and arithmetic action still available.

There is an exact calibration showing why the total degree alone cannot supply it. The family

$$G_j = I_r, \quad C = LI_r, \quad L > 0$$

has total curvature r for every L , but its logarithmic moment is

$$r \log(1 + L).$$

Each component has density

$$\frac{L}{(1 + Lt)^2},$$

and half its mass lies before $t = 1/L$. This is a declared algebraic family, not an asserted arithmetic packet.

The arithmetic work is therefore to control that concentration **using the original theta source and its relation maps**. Its curvature jets, second fundamental map, action-stable enlargement, and metric-pole contribution are now explicit quantities for doing so.

Deligne's finite-field argument supplies a model for the architecture—exceptional-fibre calculation, constituent control, then amplification—but its arithmetic integrality and strict weight estimate have not been proved for this new coherent-sheaf realization. Likewise, the calculated global image E_0 or F_A is retained rather than being relabelled as the entire arithmetic E .

S35.0.9 Verification and handoff

The new checker passed **23 exact finite test methods** normally and under `python -0`, with identical successful records. Both deliberately false controls were rejected in both modes. The tests include the derived special-fibre kernel, dual line factors, curvature sign, constituent maps, the minimal action-stable enlargement, and its determinant-metric pole.

All **36 manifest entries** of the preceding relation-moment archive verified, and its unchanged **22-method suite** passed fresh normal and optimized runs. The HTML reader was rendered and inspected at desktop and mobile widths; its displayed equation labels and local equation scrolling are retained.

The package includes a [tested eighteen-file add-only integration patch](#). No remote branch was changed, no new Lean execution is claimed, and no uniform arithmetic nonconcentration estimate is claimed.

The added machinery is now geometric in a concrete sense: a curve of the original representatives, its complete specialization and dual boundary, the minimal repair of its arithmetic action, and a determinant curvature whose logarithmic moment is exactly the endpoint cost already under study.

S36 Complete supplied logarithmic constituent and coupling calculation

Source role. Complete supplied mathematical text, retained with its original formulas and source chronology. The present integrated chapters state and prove the subsequent corrections and exact maps.

Exact revision. 501decfd268d2e9a382196f61169e9cd3fb27484b5ff03119f4855955328c864

Complete source. sources/endpoint_user_sources/LOGARITHMIC_CONSTITUENT_USER_SOURCE.txt

Source SHA-256. 501decfd268d2e9a382196f61169e9cd3fb27484b5ff03119f4855955328c864

I have now carried the previous curve through its logarithmic de Rham complex and used the resulting subobject-quotient comparison to improve the upper-volume calculation. The new quantitative term is a **subtraction computed from the coupling between an invariant arithmetic subspace and its quotient**:

$$\log \frac{V_i}{V_j} \leq \log \frac{\det G_F(1)}{\det G_F(0)} + \log \frac{\det(Q_0 + C_Q)}{\det Q_0} - \sum_{r=1}^p \frac{\text{Tr}(\Xi_F^r)}{r}.$$

Every matrix here comes from the **same original canonical representatives**. The final term is nonnegative before subtraction, and its full infinite sum recovers the exact volume. It is not a freely chosen correction or a consequence stipulated under the name “purity.”

The cohomological calculation also identifies exactly which degrees carry the arithmetic information on the auxiliary curve. That matters for using Deligne’s comparison correctly.

[Full derivation in the HTML reader](#) · [LaTeX](#) · [Formalization handoff](#) · [Complete package](#)

S36.0.1 1. The Deligne operation being applied

The operative passage remains the actual comparison

$$H_c^a(X, \mathcal{F}) \rightarrow \text{im } c_a \hookrightarrow H^a(X, \mathcal{F}).$$

Deligne’s upper and dual lower estimates meet on that **same image**, with the cohomological degree and dualizing twist retained. Neither the source nor its mixed boundary contribution is erased.

I used that structure in two concrete ways here: first, by constructing the compact-support and ordinary complexes of the connection already present in our curve; second, by carrying the original metric and arithmetic action through an invariant inclusion and its quotient.

The new argument starts with the existing coefficient square:

$$\begin{array}{ccc} G(\mathbb{Z}) & \xrightarrow{G(j)} & G(\mathbb{C}) \\ p_{\mathbb{Z}} \downarrow & & \downarrow p_{\mathbb{C}} \\ \mathbb{Z} & \xrightarrow{j} & \mathbb{C}. \end{array}$$

The target of $p_{\mathbb{Z}}$ remains infinite. The supported scalar $e = 0^\bullet$ and external absence τ remain separately represented before applying p .

For the current cyclic arithmetic module,

$$E = \mathbb{C}[S]/(\chi_{h,k}), \quad A = M_S, \quad q = \dim E,$$

retain

$$K_N = B_N O_N^{-1} B_N^*, \quad G_N = K_N^{-1}, \quad R_N = O_N^{-1} B_N^* G_N.$$

For an admitted degree pair $i \leq j$, put

$$G_0 = G_j, \quad \Delta = L_{ij} R_i - R_j, \quad C = \Delta^* O_j \Delta = G_i - G_j.$$

The original relation and orthogonality equations are

$$B_j \Delta = 0, \quad R_j^* O_j \Delta = 0.$$

They give precisely the previous family

$$R(z) = R_j + z\Delta, \quad G(z) = G_0 + |z|^2 C.$$

Every finite z retains the same full arithmetic jets and cohomology class. These are inherited source identities, not a new choice of metric.

S36.0.2 2. The compact-support and ordinary complexes are now calculated

Let

$$X = \mathbb{P}_{\mathbb{C}}^1, \quad w = z^{-1},$$

and take a specified A -invariant subspace $F \subseteq E$. In particular, the previous action-stable repair supplies

$$F_A = \sum_{a=0}^{q-1} A^a \ker \Delta.$$

Define the actual lattice

$$\mathcal{M}_F = F\mathcal{O}_X + \mathcal{O}_X(-\infty)E \subseteq E\mathcal{O}_X$$

and its logarithmic complex

$$\mathcal{K}_F = \left[\mathcal{M}_F \xrightarrow{\nabla} \mathcal{M}_F \otimes \Omega_X^1(\log \infty) \right],$$

in degrees 0, 1.

The differential is the restriction of the trivial coefficient connection. It is a map of sheaves of $\mathbb{C}$ -vector spaces satisfying the Leibniz rule. In a fixed local complement to F , its two pieces are

$$d, \quad d + \frac{dw}{w}.$$

The logarithmic construction and its residue map are standard; here the lattice, differential, and comparison maps are specified explicitly. ([The Stacks Project](#))

There are actual inclusions of complexes

$$\mathcal{K}_0 \longrightarrow \mathcal{K}_F \longrightarrow \mathcal{K}_E,$$

where

$$\mathcal{K}_0 = [E\mathcal{O}(-1) \longrightarrow E\Omega_X^1]$$

is the compact-support model, and

$$\mathcal{K}_E = [E\mathcal{O} \longrightarrow E\Omega_X^1(\log \infty)]$$

is the ordinary model.

The global result Let

$$\mathbb{T} = H^1(X, \Omega_X^1)$$

with its specified trace

$$\mathrm{tr}[dz/z] = 1, \quad dz/z = -dw/w.$$

The full calculation gives

$$\mathbb{H}^a(X, \mathcal{K}_F) = \begin{cases} F, & a = 0, \\ 0, & a = 1, \\ (E/F) \otimes \mathbb{T}, & a = 2, \\ 0, & \text{otherwise.} \end{cases}$$

Proof. A chosen coefficient complement writes the underlying complex as

$$F[\mathcal{O} \rightarrow \mathcal{O}(-1)] \oplus (E/F)[\mathcal{O}(-1) \rightarrow \mathcal{O}(-2)].$$

The two-chart Laurent calculation gives

$$H^0(\mathcal{O}) = \mathbb{C}, \quad H^a(\mathcal{O}(-1)) = 0, \quad H^1(\mathcal{O}(-2)) = \mathbb{T}.$$

These yield the displayed groups. The identifications are compatible with the original action even when the chosen complement is not invariant.

The action is therefore

$$A_F \quad \text{on degree zero}, \quad A_{E/F} \otimes I_{\mathbb{T}} \quad \text{on degree two},$$

and

$$\mathrm{Str}(f(A) \mid R\Gamma(X, \mathcal{K}_F)) = \mathrm{Tr} f(A_F) + \mathrm{Tr} f(A_{E/F}) = \mathrm{Tr} f(A).$$

Placing the coefficient object in the existing arithmetic degree k puts these contributions in degrees k and $k + 2$, both with sign $(-1)^k$.

This adds a term the degree-zero bundle calculation alone did not contain: **the quotient E/F survives in degree two.**

The compact-to-ordinary maps are now explicitly

$$0 \longrightarrow F \longrightarrow E$$

in degree zero, and

$$E \otimes \mathbb{T} \longrightarrow (E/F) \otimes \mathbb{T} \longrightarrow 0$$

in degree two.

For this constant-coefficient parameter curve, the degree-one comparison image is zero. That is a statement about this particular auxiliary connection, not about the arithmetic theta quotient Q . The full arithmetic E remains in the outer comparison complexes and their original action.

The distinction also preserves extensions. For example,

$$A = \begin{pmatrix} \rho & 1 \\ 0 & \rho \end{pmatrix}, \quad F = \mathbb{C}e_1,$$

induces multiplication by ρ on both one-dimensional constituents. Their two induced actions alone would not reconstruct the nonzero map $e_2 \mapsto e_1$. That map remains in the original coefficient sequence and in the action comparison calculated below.

The dual boundary is retained For

$$F^{\text{ann}} = \{\lambda \in E^\vee : \lambda(F) = 0\},$$

evaluation gives the actual map

$$\mathcal{M}_F \otimes \mathcal{M}_{F^{\text{ann}}} \longrightarrow \mathcal{O}_X(-\infty).$$

Its constant term vanishes at infinity, so it induces

$$\boxed{\mathcal{K}_F(E) \otimes \mathcal{K}_{F^{\text{ann}}}(E^\vee) \longrightarrow \mathcal{K}_0(\mathbb{C}).}$$

The resulting degree- a , degree- $(2-a)$ pairings are the perfect pairings

$$F \otimes (E^\vee / F^{\text{ann}}) \rightarrow \mathbb{C}, \quad (E/F) \otimes F^{\text{ann}} \rightarrow \mathbb{C},$$

with $\mathbb{T}$ and its residue orientation retained.

The note also gives the explicit conjugation map from the linear dual to the metric antidual. Thus the original $kI - A^*$ antidual action is not substituted for a linear transpose without its coefficient map.

S36.0.3 3. Higher layers remain above the same split support

For every positive integer r , the same construction gives

$$\mathcal{M}_{F,r} = F\mathcal{O}_X + \mathcal{O}_X(-r\infty)E.$$

Its modified connection has residue r :

$$d + r \frac{dw}{w}.$$

The quotient comparing level r with level one has the actual coefficient basis

$$w, w^2, \dots, w^{r-1}$$

in both degrees, with differential

$$\boxed{\text{diag}(1, 2, \dots, r-1).}$$

Its inverse is the explicit contracting homotopy. The higher coefficient classes are present; their vanishing in cohomology follows from this differential.

This divisor-depth calculation is connected to the original conormal-depth calculation by

$$\boxed{\frac{\mathbb{C}[w] \otimes \mathcal{P}}{(w^r) + I^a(\mathbb{C}[w] \otimes \mathcal{P})} \xrightarrow{\sim} (\mathbb{C}[w]/w^r) \otimes (\mathcal{P}/I^a),}$$

where

$$\mathcal{P} = \mathbb{C}[s_1, \dots, s_k], \quad I = (h(s_1), \dots, h(s_k)).$$

The map sends $[f(w)P]$ to $[f] \otimes [P]$; its inverse multiplies the representatives.

Restriction and differentiation in the two directions therefore have their actual commuting maps. The two depth indices are retained independently, over the same scalar G -construction.

When a relation vanishes, its split lift lands at its receiving fibre's zero. This is the original internal-homology operation, which keeps both the source class and the comparison kernel available.

S36.0.4 4. Carry the original metric through an invariant arithmetic quotient

This is the new quantitative part.

Keep the actual invariant maps

$$I : F \hookrightarrow E, \quad AI = IA_F,$$

$$\pi : E \twoheadrightarrow E/F, \quad \pi A = A_Q \pi.$$

Write $t = |z|^2$, so

$$G(t) = G_0 + tC.$$

Choose any fixed coefficient lift $\overline{H} : E/F \rightarrow E$. Its **specified G_0 -orthogonal lift** is

$$H_0 = \overline{H} - I(I^*G_0I)^{-1}I^*G_0\overline{H}.$$

It satisfies

$$\pi H_0 = I, \quad I^*G_0H_0 = 0.$$

Define

$$G_{F,0} = I^*G_0I, \quad C_F = I^*CI,$$

$$D_F = I^*CH_0, \quad Q_0 = H_0^*G_0H_0, \quad C_Q = H_0^*CH_0.$$

In the actual coefficient coordinates $[I, H_0]$, the original metric is

$$\begin{pmatrix} G_{F,0} + tC_F & tD_F \\ tD_F^* & Q_0 + tC_Q \end{pmatrix}.$$

Now set

$$G_F(t) = G_{F,0} + tC_F,$$

$$H_t = H_0 - tIG_F(t)^{-1}D_F.$$

Then

$$\pi H_t = I, \quad I^*G(t)H_t = 0,$$

and the actual quotient metric is

$$Q(t) = H_t^*G(t)H_t = Q_0 + tC_Q - t^2D_F^*G_F(t)^{-1}D_F.$$

The correction $H_t - H_0$ lies in F . The full map $[I, H_t]$ remains invertible and retains that subspace. It is not a declaration that F is a theta boundary.

The coupling has an exact sign and size Define

$$\beta_t = G_F(t)^{-1} I^* C H_t : E/F \rightarrow F.$$

Differentiating the displayed maps gives

$$H'_t = -I\beta_t, \quad Q'(t) = H_t^* C H_t, \quad Q''(t) = -2\beta_t^* G_F(t) \beta_t.$$

For the first metric derivative, the terms containing H'_t vanish by orthogonality. Differentiating once more gives the last equation, with its minus sign and factor two.

Integrating with the original endpoints retained proves

$$D_F^* G_F(1)^{-1} D_F = 2 \int_0^1 (1-t) \beta_t^* G_F(t) \beta_t dt.$$

The subtraction in the quotient metric is therefore exactly an integrated squared coupling map. Its finite matrix formula defines it without requiring a new numerical quadrature.

S36.0.5 5. The same arithmetic action and theta relation reach this quotient

The actual lift defect is the map $a_t : E/F \rightarrow F$ defined by

$$A H_t - H_t A_Q = I a_t.$$

Differentiation gives

$$a'_t = \beta_t A_Q - A_F \beta_t.$$

Thus the metric coupling is related to the original arithmetic action through a concrete Sylvester map. On distinct primary blocks, the note constructs its finite inverse, retaining every power of the nilpotent parts. At coincident primary values, it retains the map with its kernel and image instead of using a nonexistent inverse.

For the original control form

$$W(t) = A^* G(t) + G(t) A - k G(t),$$

both comparisons are exact:

$$I^* W(t) I = A_F^* G_F(t) + G_F(t) A_F - k G_F(t),$$

$$H_t^* W(t) H_t = A_Q^* Q(t) + Q(t) A_Q - k Q(t).$$

The second equation uses $H_t^* G(t) I = 0$, not invariance of the orthogonal complement.

At the original test-function level,

$$D^{(k)} \mathcal{V} R(z) H_t - \mathcal{V} R(z) H_t A_Q = dK(z) H_t + \mathcal{V} R(z) I a_t.$$

The first term is the original theta boundary. The second belongs to the retained arithmetic subspace F , and becomes zero only under the further quotient by that included subspace. Both terms, and their different quotient maps, remain in the calculation.

This is the source-level connection between the constituent calculation and the original e -valued relation.

S36.0.6 6. The resulting upper bound keeps the extension contribution

At the endpoint, put

$$Q_+ = Q_0 + C_Q, \quad \Pi_F = D_F^* G_F(1)^{-1} D_F, \quad \boxed{\Xi_F = Q_+^{-1} \Pi_F.}$$

The source proves

$$Q_+ \succ 0, \quad Q(1) = Q_+ - \Pi_F \succ 0.$$

Hence Ξ_F is positive self-adjoint in Q_+ , with eigenvalues in $[0, 1)$.

The determinant of the coefficient transition $[I, H_0] \rightarrow [I, H_t]$ is independent of t . Taking determinants of the original metric therefore gives

$$\boxed{\log \frac{V_i}{V_j} = \log \frac{\det G_F(1)}{\det G_F(0)} + \log \frac{\det Q_+}{\det Q_0} + \log \det(I - \Xi_F).}$$

Now

$$-\log \det(I - \Xi_F) = \sum_{r=1}^{\infty} \frac{\text{Tr}(\Xi_F^r)}{r},$$

with nonnegative terms. Retaining the first p proves

$$\boxed{\log \frac{V_i}{V_j} \leq \log \frac{\det G_F(1)}{\det G_F(0)} + \log \frac{\det Q_+}{\det Q_0} - \sum_{r=1}^p \frac{\text{Tr}(\Xi_F^r)}{r}.}$$

The upper bounds decrease to the exact volume. No separately assumed uniform restriction gap is needed to justify a finite subtraction.

The two positive terms can themselves be bounded by the previous two-trace certificate, applied to the actual compressed operators

$$Z_F = G_{F,0}^{-1} C_F, \quad Z_Q = Q_0^{-1} C_Q.$$

Writing that established majorant as U , the combined result is

$$\boxed{\log \frac{V_i}{V_j} \leq U(Z_F) + U(Z_Q) - \sum_{r=1}^p \frac{\text{Tr}(\Xi_F^r)}{r}.}$$

This uses the invariant subobject and quotient without estimating them as independent, uncoupled objects.

An exact improvement on the same source fixture For the preceding mass-seven Gaussian calibration,

$$\chi = (S-1)^3, \quad \omega_n = 7n!, \quad (i, j) = (3, 6),$$

take the actual invariant line generated by $(S-1)^2$.

The calculated matrices give

$$\frac{\det G_F(1)}{\det G_F(0)} = \frac{63}{8}, \quad \frac{\det Q_+}{\det Q_0} = \frac{245}{32},$$

and

$$\Xi_F = \begin{pmatrix} 2/3 & 2/3 \\ 0 & 0 \end{pmatrix}.$$

This matrix is self-adjoint in Q_+ , with eigenvalues $2/3, 0$.

The exact original loss is

$$\log(V_3/V_6) = \log(5145/256) = 3.000603203788587506 \dots$$

Four terms of the new subtraction give

$$\log(V_3/V_6) \leq \log(15435/256) - \frac{28}{27} = 3.062178455419660160 \dots$$

The preceding full two-trace bound was approximately 3.063328308618.

This is a strict improvement on that **same canonical source and metric**. It is a declared finite calibration, not an asserted zeta packet or an asymptotic estimate.

S36.0.7 7. The bound is composed with the existing endpoint theorem

Let $\mathcal{U}_{ij}$ be either new upper expression. The inherited consecutive-window theorem gives

$$\min_{i \leq N < j} \epsilon_N \leq \left(\frac{\omega_j}{\omega_i} \right)^{1/(2(j-i))} \exp \left(\frac{\mathcal{U}_{ij}}{2(j-i)} \right).$$

The selected degree belongs to the existing canonical family. No metric is selected again after estimating it.

For either original quartet block, the supplied arithmetic norm estimate bounds the first factor by $C_h^{\text{win}} q_k$. The other session's finite propagation and written analytic composition retain the lower cost

$$2q_k \log(D_h k)$$

for each block, and the combined limiting threshold four.

The present calculation therefore gives a constituent-level upper side of those **same inequalities**, including a negative coupling contribution that was previously unavailable in that form.

The regular extension at infinity is accounted for as well. Passing to the residue-zero extension gives, with the original metric retained,

$$c_1((\det E\mathcal{O}_X)^\vee) = \mu_{ij} - \text{rank}(C) \delta_\infty.$$

The positive curvature measure and its logarithmic moment remain. The boundary atom makes the total degree zero; it does not make that logarithmic moment small.

That is why this continuation uses the actual subquotient estimate rather than inferring arithmetic purity from the compactification's integer degree.

S36.0.8 Verification and current result

I checked GitHub main at 1f7e7c02343884a17df9873566e81a9083c70951; its current four-volume source retains the same threshold and proof scope.

The new checker passed **16 exact finite test methods**, normally and under python -0, with identical successful records. Both deliberately false controls failed in both modes. The parent specialization-curvature archive's **41 manifest entries** verified, and its unchanged **23-method suite** passed fresh normal and optimized runs.

The supplied Deligne archive was reassembled and hash-checked; the relevant LaTeX and page-local text passages were read. No PDF extraction or OCR was used. The HTML reader was rendered and inspected at desktop and mobile widths.

The package includes a **tested 23-file add-only integration patch**. No remote branch was changed, and no new Lean certificate is claimed.

The completed advance is the actual logarithmic comparison, its retained degree-two and dual boundary information, and an upper-volume estimate that uses the calculated coupling between arithmetic constituents. A uniform bound below the inherited quartet threshold is still not established. The quantitative work is now focused on the original compressed source matrices and that explicit subtraction—not on assigning purity to a curve merely because it has been compactified.

S37 Complete exact restriction fixture and its source maps

Source role. Full finite-calibration derivation with original masses, every map and the exact scope of its executed checks.

Exact revision. f5ef0746d22ba641aa2fd0d50c0f19954fe9c367d8cacd0206aa1e28f6702b29

Complete source. sources/local_endpoint_continuations/endpoint_restriction_join_fixture_20260913.md

Source SHA-256. f5ef0746d22ba641aa2fd0d50c0f19954fe9c367d8cacd0206aa1e28f6702b29

S37.1 Exact lower-source gap and two-pair restriction certificates

This is a complete finite calculation for the explicitly declared auxiliary source below. It joins the lower-source comparison in AU.11–29 to the restriction and trace construction in equations (24), (34), and (47)–(51) of the supplied restriction note. The original coordinate is $S=1+iu$, the relation is $\chi(S)=S^2-2S-1$, the quotient has dimension two, and the source mass is exactly $9/16$.

The result is an explicit lower gap $108/763$ obtained from a positive source comparison and an exact remainder operator norm. The actual sharp gap is $135/331$. Both apply to the two pairs (1,3) and (2,4). Their trace certificates are computed with exact rational logarithm enclosures. These are finite conclusions for this specified source; no estimate for a growing arithmetic quartet family is inferred.

S37.1.1 1. Source, lower source, and literal masses

For positive integer λ define

$$r_\lambda(u) = \frac{|\Gamma(\lambda + iu/2)|^2}{2\pi}, \quad c_\lambda = 2^{1-2\lambda}\Gamma(2\lambda).$$

The measures used here are

$$w(t) = \left(1 + \frac{t^2}{4}\right) r_1(t) = r_2(t), \quad m = w * w = \frac{1}{70} r_4, \quad v = r_1 * r_1 = \frac{1}{3} r_2, \quad d\nu = \frac{54}{35} v(u) du. \quad (\text{F.1})$$

Here is the measure identity with its constants. Euler's gamma integral gives $\Gamma(z+1)=z \Gamma(z)$ by integration by parts when $\Re z > 0$. Multiplying this equality by its conjugate proves the first equality in (F.1). The change from two positive gamma-integral variables to their sum and ratio, with Jacobian equal to the sum, gives

$$\Gamma(a)\Gamma(b) = \Gamma(a+b) \int_0^1 x^{a-1}(1-x)^{b-1} dx, \quad \Re a, \Re b > 0.$$

Set $a=\lambda+iu/2$, $b=\lambda-iu/2$, and then $x=e^t/(1+e^t)$. This gives

$$|\Gamma(\lambda + iu/2)|^2 = \Gamma(2\lambda) \int_{\mathbb{R}} (2 \cosh(t/2))^{-2\lambda} e^{iut/2} dt.$$

After $t=2y$, Fourier inversion, with convention $\hat{f}(t)=\int_{\mathbb{R}} f(u)e^{-itu}du$, proves

$$\hat{r}_\lambda(t) = 2\Gamma(2\lambda)(2 \cosh t)^{-2\lambda} = c_\lambda(\cosh t)^{-2\lambda}. \quad (\text{F.2})$$

All inversions and moment differentiations used here are legitimate. The integrand $(2 \cosh y)^{-2\lambda}$ and every derivative decay exponentially on the real axis. For each $0 < a < \pi/2$, it is holomorphic on the closed strip $|\Im y| < a$; shifting the Fourier integral up or down inside that strip bounds $r_\lambda(u)$ by a constant times $\exp(-a|u|)$. The vertical sides of a rectangular contour tend to zero because the integrand decays exponentially in $|\Re y|$, uniformly in that strip. Thus every polynomial moment exists, the Fourier transform extends to imaginary arguments near zero, and its moment-generating function is

$$\int e^{tu} r_\lambda(u) du = c_\lambda(\cos t)^{-2\lambda}, \quad |t| < \pi/2.$$

Multiplying (F.2) proves

$$r_a * r_b = \frac{c_a c_b}{c_{a+b}} r_{a+b}.$$

The constants are $c_1=1/2$, $c_2=3/4$, and $c_4=315/8$. Consequently the masses of w, m, v, ν are respectively

$$\left[\frac{3}{4}, \frac{9}{16}, \frac{1}{4}, \frac{27}{70} \right] \quad (\text{F.3})$$

Two applications of the gamma recurrence give the pointwise identity

$$m(u) = \left(\frac{54}{35} + \frac{39u^2}{280} + \frac{3u^4}{1120} \right) v(u). \quad (\text{F.4})$$

Indeed $r_4/r_2=(4+u^2/4)(9+u^2/4)$ and $(r_4/70)/(r_2/3)$ multiplies that product by $3/70$. Every coefficient in (F.4) is retained. Since $v(u) > 0$, this proves $d\nu \leq m(u)du$ and hence the contraction

$$\mathbb{C}[S]_{\leq j} \longrightarrow \mathbb{C}[S]_{\leq j}, \quad P \longmapsto P, \quad \|P\|_\nu^2 \leq \|P\|_m^2. \quad (\text{F.5})$$

The forms in (F.5) integrate $|p(1+iu)|^2$. The polynomial map, quotient map, and original coordinate are unchanged.

The even moments of m through degree eight are

$$(9/16, 9/2, 117, 5472, 385272),$$

and those of v are

$$(1/4, 1, 14, 376, 16064). \quad (\text{F.6})$$

The ν moments are the latter multiplied by $54/35$; all odd moments are zero. These values follow by differentiating the functions in (F.2). The executable constructs them by the equivalent finite multiplication recurrence

$$ub_j = b_{j+1} + j(j + \alpha - 1)b_{j-1}, \quad \alpha = 2\lambda,$$

starting from $b_0=1$, retaining the coefficient of b_0 and multiplying by the literal mass. On the finite degrees needed here it also verifies them by two independent constructions: binomial convolution of $(1+t^2/4)r_1$ moments, and the full three-term density (F.4). The monic-polynomial orthogonality needed below is verified directly against every Gram entry, so no unchecked infinite recurrence is used as a finite matrix certificate.

S37.1.2 2. Complete original-coordinate matrices

The polynomial space has ordered basis $1, S, \dots, S^N$. Its conjugate-linear-first Gram is

$$(H_N)_{ab} = \sum_{x=0}^a \sum_{y=0}^b \binom{a}{x} \binom{b}{y} (-1)^x i^{x+y} m_{x+y}. \quad (\text{F.7})$$

The imaginary terms vanish for the stated even source and are separately accumulated and checked in the executable. The full largest matrices are

$$H_4 = \frac{1}{16} \begin{pmatrix} 9 & 9 & -63 & -207 & 1449 \\ 9 & 81 & 81 & -1863 & -5751 \\ -63 & 81 & 2025 & 2025 & -89343 \\ -207 & -1863 & 2025 & 93393 & 93393 \\ 1449 & -5751 & -89343 & 93393 & 6526089 \end{pmatrix}, \quad (\text{F.8})$$

$$H_4^\vee = \frac{1}{70} \begin{pmatrix} 27 & 27 & -81 & -297 & 891 \\ 27 & 135 & 135 & -1485 & -4725 \\ -81 & 135 & 1755 & 1755 & -41985 \\ -297 & -1485 & 1755 & 45495 & 45495 \\ 891 & -4725 & -41985 & 45495 & 1906875 \end{pmatrix}. \quad (\text{F.9})$$

Every smaller source form is the corresponding leading principal submatrix. The polynomial relation yields

$$J_1 = I_2, \quad J_2 = \begin{pmatrix} 1 & 0 & 1 \\ 0 & 1 & 2 \end{pmatrix}, \quad J_3 = \begin{pmatrix} 1 & 0 & 1 & 2 \\ 0 & 1 & 2 & 5 \end{pmatrix}, \quad J_4 = \begin{pmatrix} 1 & 0 & 1 & 2 & 5 \\ 0 & 1 & 2 & 5 & 12 \end{pmatrix}. \quad (\text{F.10})$$

These are the maps to coefficients in $E = \mathbb{C}[S]/(\chi)$ with basis $(1, S)$. The recurrence for their columns is $J_{-1}(\cdot, a) = 2J_{-1}(\cdot, a-1) + J_{-1}(\cdot, a-2)$, exactly the relation $S^2 = 2S + 1$.

For each degree define

$$K_N = J_N H_N^{-1} J_N^*, \quad G_N = K_N^{-1}, \quad R_N = H_N^{-1} J_N^* G_N, \quad V_N = \det G_N. \quad (\text{F.11})$$

Positivity of the density proves $H_N > 0$. Surjectivity of J_N proves $K_N > 0$. Direct multiplication gives $J_N R_N = I$ and $R_N^* H_N R_N = G_N$. For any z with $J_N z = 0$, $z^* H_N R_N = z^* J_N^* G_N = 0$. Therefore every representative $R_N x + z$ has squared norm $x^* G_N x + z^* H_N z$, proving its minimum property on the original quotient fibre.

For transparent scalar calculations introduce the explicitly typed coordinate isomorphism

$$\mathbb{C}[x]/(x^2 - 2) \xrightarrow{\sim} E, \quad [x] \mapsto [S - 1], \quad C = \begin{pmatrix} 1 & -1 \\ 0 & 1 \end{pmatrix}, \quad (1, S)C = (1, S - 1). \quad (\text{F.12})$$

Its inverse substitutes $S = x + 1$. Its determinant is one. The source observation of x is still iu , with its sign and phase retained. A quotient form transforms by $G_x = C^* G_S C$; its inverse transforms by $K_x = C^{-1} K_S C^{-*}$. No measure is changed by these identities.

The following finite polynomials and norms follow by substitution into (F.6)–(F.9). They are monic in S ; writing them in $x = S - 1$ is only (F.12).

Degree	Original source polynomial	Squared norm	Remainder in $(1, x)$
0	1	9/16	1
1	x	9/2	x
2	$x^2 + 8$	81	10
3	$x^3 + 26x$	2430	28x
4	$x^4 + 56x^2 + 240$	106920	356

Degree	Lower-source polynomial	Squared norm	Remainder in $(1, x)$
0	1	27/70	1
1	x	54/35	x
2	$x^2 + 4$	108/7	6
3	$x^3 + 14x$	1944/7	16x
4	$x^4 + 32x^2 + 72$	7776	140

Let P_N have these original S coefficient columns and let O_N be the diagonal of their squared norms. The checked identity is the full matrix equation $P_N^* H_N P_N = O_N$. Its inverse and (F.11) give

$$K_N = (J_N P_N) O_N^{-1} (J_N P_N)^*. \quad (\text{F.13})$$

Thus the inverse quotient form is the sum of each listed remainder outer product divided by its original norm. Explicitly,

$$\begin{aligned}
K_{1,x} &= \text{diag}(16/9, 2/9), & K_{2,x} &= \text{diag}(244/81, 2/9), \\
K_{3,x} &= \text{diag}(244/81, 662/1215), & K_{4,x} &= \text{diag}(56102/13365, 662/1215), \\
K_{3,x}^\nu &= \text{diag}(133/27, 763/486), & K_{4,x}^\nu &= \text{diag}(3619/486, 763/486).
\end{aligned} \tag{F.14}$$

The full original-basis matrices and least representatives at all four degrees are included as rational entries in the JSON. Equations (F.8)–(F.11) are their complete finite construction. Their quotient volumes are

$$V_1 = 81/32, \quad V_2 = 729/488, \quad V_3 = 98415/161528, \quad V_4 = 16238475/37139524. \tag{F.15}$$

S37.1.3 3. A proved gap from the exact remainder operator

Let $B=H_1$, the norm on the unique representative of degree below two. In (F.12),

$$B_x = C^*BC = \text{diag}(9/16, 9/2).$$

Consider the actual remainder operator

$$\mathcal{R}_j : (\mathbb{C}[S]_{\leq j}, H_j^\nu) \longrightarrow (\mathbb{C}[S]_{\leq 1}, B), \quad P \longmapsto \text{rem}_\chi P, \quad j = 3, 4. \tag{F.16}$$

Its coefficient matrix is exactly J_j . Its squared norm is the greatest eigenvalue of $B^{\wedge\{1/2\}} J_j (H_j^\nu)^{\wedge\{-1\}} J_j^* B^{\wedge\{1/2\}}$. To see this, the substitutions $a=(H_j^\nu)^{\wedge\{1/2\}}v$ and $b=B^{\wedge\{1/2\}}J_j v$ transport its norm ratio to the Euclidean operator $B^{\wedge\{1/2\}} J_j (H_j^\nu)^{\wedge\{-1\}}$. For a matrix L , its greatest squared singular value is the greatest eigenvalue of LL^* : the nonzero spectra of L^*L and LL^* coincide by the maps L and L^* , and maximization of the positive Hermitian quadratic form is diagonalization by an orthonormal eigenbasis.

By (F.14), these positive eigenvalues are exactly

j	first	second
3	133/48	763/108
4	3619/864	763/108.

Both first entries are smaller than the second: the differences are 1855/432 and 2485/864. Consequently

$$\boxed{\|\mathcal{R}_3\|^2 = \|\mathcal{R}_4\|^2 = \frac{763}{108}.} \tag{F.17}$$

This norm is attained. In the original S coefficient basis use

$$f_3(S) = -\frac{245}{36} + \frac{791}{108}S - \frac{7}{9}S^2 + \frac{7}{27}S^3, \quad f_4 = f_3 \in \mathbb{C}[S]_{\leq 4}. \tag{F.18}$$

This is $f_j=(H_j^\nu)^{\wedge\{-1\}}J_j^*B(-1,1)^{\wedge\tau}$; the two expressions agree by direct multiplication of the matrices (F.8)–(F.10). The norm and remainder norm are

$$\|f_j\|_\nu^2 = \frac{763}{24}, \quad \|\text{rem}_\chi f_j\|_B^2 = \frac{582169}{2592},$$

whose ratio is 763/108. This supplies a concrete extremizing polynomial, in addition to the complete matrix certificate

$$\frac{763}{108}H_j^\nu - J_j^*BJ_j \succeq 0. \tag{F.19}$$

The JSON records every principal minor of (F.19), including its zero minors. For a Hermitian matrix, non-negativity of all principal minors implies positive semidefiniteness: the coefficients of $\det(tI+A)$ are the sums of its principal minors of each size, so this polynomial is strictly positive for $t>0$; a negative eigenvalue of A would give a positive root. This proves the exact PSD validation criterion used here without a floating-point eigenvalue.

The source contraction (F.5) now gives

$$\|\text{rem}_x P\|_B^2 \leq \frac{763}{108} \|P\|_\nu^2 \leq \frac{763}{108} \|P\|_m^2. \quad (\text{F.20})$$

Apply this to the actual least representative R_{jx} . Its remainder is x , so

$$G_j \succeq \frac{108}{763} B.$$

The degree-one remainder is an admitted representative for every $i \geq 1$, hence $G_{i \leq B}$ by the minimum property. Therefore for $(i,j)=(1,3),(2,4)$,

$$\boxed{G_j \succeq \frac{108}{763} G_i, \quad K_i \succeq \frac{108}{763} K_j.} \quad (\text{F.21})$$

The inverse inequality follows by conjugating the first by $G_{i \leq -1/2}$, inverting its positive eigenvalues, and transporting back. The gap $108/763$ is thus obtained from the explicitly proved source comparison and exact remainder norm. Its construction uses the low-degree actual form B and the declared comparison moments through degree eight.

S37.1.4 4. Restriction in the original polynomial coordinates

Define the typed restriction on the same quotient by

$$T_{i,j} : (E, G_j) \longrightarrow (E, G_i), \quad T_{i,j} = K_i G_j. \quad (\text{F.22})$$

For x, y in E , $x^* G_{jy} = x^* G_{iT_{i,j}y}$; this proves it is the adjoint of identity transport $(E, G_i) \rightarrow (E, G_j)$. In the original $(1, S)$ coordinates the two return maps are

$$T_{1,3} = \begin{pmatrix} 36/61 & 3681/20191 \\ 0 & 135/331 \end{pmatrix}, \quad T_{2,4} = \begin{pmatrix} 20130/28051 & 2876145/9284881 \\ 0 & 135/331 \end{pmatrix}. \quad (\text{F.23})$$

The coordinate matrices in (F.12) diagonalize these endomorphisms by $T_x = C^{-1} T_{SC}$, giving spectra

$$\{36/61, 135/331\}, \quad \{20130/28051, 135/331\}. \quad (\text{F.24})$$

Both eigenvalues in each pair lie in $(0,1)$. The smallest is $135/331$ for both pairs, and hence this is the exact best scalar in $\kappa_{i \geq g} \kappa_j$ for these actual source forms. It is stronger than (F.21), through the strictly positive difference $135/331 - 108/763$.

Let $L_{\{i,j\}}$ pad original polynomial coefficients with zeros. Since $P_j^* H_j P_j = 0_j$, the orthogonal projection from degree j to degrees at most i is the endomorphism

$$Q_{i,j} = P_j \text{diag}(\underbrace{1, \dots, 1}_{i+1}, 0, \dots, 0) P_j^{-1}. \quad (\text{F.25})$$

Its range is $L_{\{i,j\}} P_i$; direct multiplication proves $Q^2 = Q$ and $Q^* H_j = H_j Q$. In the two original S coordinate spaces these are

$$Q_{1,3} = \begin{pmatrix} 1 & 0 & -9 & 0 \\ 0 & 1 & 2 & -23 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix},$$

$$Q_{2,4} = \begin{pmatrix} 1 & 0 & 0 & 27 & -189 \\ 0 & 1 & 0 & -29 & 0 \\ 0 & 0 & 1 & 3 & -50 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix}. \quad (\text{F.26})$$

In monic polynomial coordinates the first $i+1$ rows of the degree- j least lift are $0_{i \leq -1} (J_i P_i)^* G_j$; multiplication of the degree- i lift by $T_{\{i,j\}}$ gives precisely that expression because $G_i K_i = I$. Transporting by the original coefficient matrices therefore proves

$$\boxed{L_{i,j}R_iT_{i,j} = Q_{i,j}R_j.} \quad (\text{F.27})$$

Its Gram is $G_jK_iG_j$. For an eigenvector v of T with eigenvalue g , this becomes

$$\frac{\|Q_{i,j}R_jv\|_{H_j}^2}{\|R_jv\|_{H_j}^2} = g, \quad \frac{\|(I - Q_{i,j})R_jv\|_{H_j}^2}{\|R_jv\|_{H_j}^2} = 1 - g. \quad (\text{F.28})$$

The second equation follows from orthogonal decomposition by (F.25). The same original representative determines both quantities.

Writing $D = L_{\{i,j\}}R_i - R_j$ and $H = I - T_{\{i,j\}}$, equation (F.27) gives the exact correction

$$D = L_{i,j}R_iH - (I - Q_{i,j})R_j, \quad J_jD = 0, \quad D^*H_jD = G_i - G_j. \quad (\text{F.29})$$

The remainder equation follows from $J_jL_{\{i,j\}}R_i = J_jR_j = I$. For the Gram identity, R_j is orthogonal to every relation in $\ker J_j$ by (F.11), so $L_{\{i,j\}}R_i = R_j + D$ is an orthogonal sum. The return maps compose by $K_iG_jK_jG_i = K_iG_i$.

The quotient multiplication action is retained as

$$A = \begin{pmatrix} 0 & 1 \\ 1 & 2 \end{pmatrix}.$$

For $W_N = A^*G_N + G_{NA} - 2G_N$ and $H_N = K_{NW}_N$, expansion gives

$$AT - TA = H_iT - TH_j. \quad (\text{F.30})$$

Indeed the two terms $K_iA^*G_j$ and the two terms $2K_iG_j$ cancel. This records the exact action defect of the return map. Each finite matrix equation (F.27), (F.29), and (F.30) is checked in the literal original coordinates.

S37.1.5 5. Full finite logarithmic certificates

The determinant identity in (F.22) is

$$\det T_{i,j} = V_j/V_i.$$

Since the two positive eigenvalues are (F.24), put $s_a = \text{Tr}(I - T)^a$. Expansion of $-\log g = \sum_{a=1}^{\infty} (1-g)^a/a$ proves

$$\mathcal{L}_{i,j} = \log(V_i/V_j) = \sum_{a \geq 1} \frac{s_a}{a}. \quad (\text{F.31})$$

For any of the proved lower gaps g_0 , let $r = 1 - g_0$. Each loss eigenvalue $x = 1 - g$ satisfies $0 < x < r < 1$. The exact tail comparison is

$$\sum_{a=p+1}^{\infty} \frac{x^a}{a} = x^{p+1} \sum_{a=p+1}^{\infty} \frac{x^{a-p-1}}{a} \leq x^{p+1} \frac{-\log g_0 - \sum_{a=1}^p r^a/a}{r^{p+1}}.$$

Thus

$$\sum_{a=1}^p \frac{s_a}{a} \leq \mathcal{L}_{i,j} \leq U_p(H, g_0) := \sum_{a=1}^p \frac{s_a}{a} + \frac{-\log g_0 - \sum_{a=1}^p r^a/a}{r^{p+1}} s_{p+1}. \quad (\text{F.32})$$

For these finite pairs, the executable computes every trace through power six directly by matrix multiplication and independently from the rational spectrum. Its exact first three values are:

Pair	s_1	s_2	s_3
(1,3)	20231/20191	211421561/407676481	2275697407691/8231395827871
(2,4)	8119847/9284881	37102062682217/86209015184161	184216076205697661987/800440447112127969841

The two determinant ratios and their product are

$$\frac{V_1}{V_3} = \frac{20191}{4860}, \quad \frac{V_2}{V_4} = \frac{9284881}{2717550}, \quad \boxed{\frac{V_1 V_2}{V_3 V_4} = \frac{3073295611}{216513000}}. \quad (\text{F.33})$$

All logarithms in (F.31)–(F.32) have rational arguments. The executable uses exact rational enclosures. For $1 < y < 2$, put $t = (y-1)/(y+1)$. Integrating the geometric series $2/(1-t^2) = 2 \sum_{a \geq 0} t^{2a}$ from zero gives

$$2 \sum_{a=0}^{M-1} \frac{t^{2a+1}}{2a+1} \leq \log y \leq 2 \sum_{a=0}^{M-1} \frac{t^{2a+1}}{2a+1} + \frac{2t^{2M+1}}{(2M+1)(1-t^2)}. \quad (\text{F.34})$$

The upper tail follows by replacing all positive denominators by the first denominator and summing the geometric series. For $z \geq 1$, finite multiplication writes $z = 2^e y$ with $1 < y < 2$, and $\log z = e \log 2 + \log y$ transports the two intervals. For $z < 1$, $\log z = -\log(1/z)$ reverses interval endpoints. These are exact scalar logarithm identities; the source measures remain (F.1). The script uses $M=90$, checks loss widths below 10^{-70} , and checks certificate widths below 10^{-65} . Every enclosure endpoint and exact tail coefficient is retained in the JSON.

For a compact rational display, all following intervals have denominator 10^{15} . Their endpoints were obtained by outward integer rounding of the saved exact fractions, retaining the correct inequalities:

Quantity	Lower numerator	Upper numerator
$\log(V_1 V_2 / (V_3 V_4))$	2652855161899890	2652855161899891
Sum of $p=2$ upper certificates using 108/763	2934134222167925	2934134222167926
Sum of $p=2$ upper certificates using 135/331	2666680039877747	2666680039877748

The exact old direct trace bound is

$$\text{Tr}(G_1(K_3 - K_1)) + \text{Tr}(G_2(K_4 - K_2)) = \frac{1159}{540} + \frac{334321}{181170} = \frac{1446331}{362340}. \quad (\text{F.35})$$

To prove it bounds the loss, diagonalize $G_i^{-1/2} K_j G_i^{-1/2}$, whose eigenvalues are $1/g$; the scalar inequality $\log x \leq x-1$ for $x \geq 1$ follows by integrating $1/t \leq 1$ from one. Summing gives (F.35). Exact rational comparison verifies that each new $p=2$ total upper bound is strictly below (F.35), and that the sharp-gap certificate is strictly below the lower-source-gap certificate.

The cost of using the explicit lower-source gap can also be inspected pair by pair. The intervals below again have denominator 10^{15} and enclose the excess $U_{2-\text{mathcal{L}}}$:

Pair and gap	Lower numerator	Upper numerator
(1,3), lower-source 108/763	155314375058502	155314375058503
(2,4), lower-source 108/763	125964685209532	125964685209533
(1,3), actual 135/331	9359847652264	9359847652265
(2,4), actual 135/331	4465030325591	4465030325592

The script additionally computes the exact (F.32) enclosures for $p=1,3,5$. Each is checked against the independently enclosed determinant logarithm. These finitely many calculations make no claim about a uniform gap in a tensor-degree limit.

S37.1.6 6. Complete executable replay and provenance

Only these three files were authored for this lane:

- `endpoint_restriction_join_fixture_20260913.py`: complete standard-library rational calculation and subprocess driver.
- `endpoint_restriction_join_fixture_20260913.json`: all matrices, principal minors, witnesses, trace coefficients, logarithm enclosures, check labels, full stdout/stderr, actual commands, timings, return codes, and hashes for every subprocess.
- This Markdown proof and local continuity record.

The complete positive run contains **303 distinct mathematical checks**. The driver ran the positive calculation and seven changed calculations in both ordinary Python and `python -O`: **16 actual complete subprocess jobs**. Every job reaches all 303 checks. Assertions are not used as tests, and no changed computation is rejected by a startup guard or deliberately raised exception. The changed computations fail at the following counts, identically in both modes:

Changed calculation	Failed checks
Set the actual source mass to one	20
Set the lower-source mass to one	30
Replace K_{iG_j} by the reverse K_{jG_i}	36
Truncate original monomial coefficients in place of the orthogonal projection	8
Use the smaller comparison eigenvalue as the remainder norm cap	24
Replace trace of a power by power of the trace	23
Use denominator r^p in place of $r^{(p+1)}$ in the logarithmic tail coefficient	24

Each unchanged run has zero failures and exit code zero; each changed run has the listed positive failure count and exit code one. The driver separately checks full counts, unique labels, outcomes, return codes, empty stderr, and equality of complete result objects between ordinary and optimized modes. These execution/provenance checks and repeated runs do not increase the count of distinct mathematical checks.

The mathematical inputs were read completely before construction:

- `arithmetic_volume_upper_route_20260913.tex`, SHA256 21aaedc3585887fa7d2cb3e37e68d14415829a4b213566f7a08f4619835ef38b.
- Supplied `Tau_Endpoint_Restriction_Control/NOTE.tex`, SHA256 ff4cc53cb4d3b10a9547a8a2365db7fd5d874bf1ecf7dd8542b8d1f05f433ef6.
- Earlier auxiliary-source proof `gamma_endpoint_window_bridge_fixture_20260913.md`, SHA256 05108b93cfd1e15e782f171f37569e3d77c8c4775b1bf8349f4021a0eb4315ed.

No existing executable was imported into this fixture. An independent mathematical reviewer derived the same source moments, remainder kernels, comparison eigenvalues, both original-coordinate return matrices, and exact trace values without importing this script or writing files.

The completed independent read-only audit found no defect. It read all 415 script lines and inspected the normal result and all 16 replay outcomes. Its separate calculation passed **170 audit predicates** without importing or running this fixture script. It reconstructed the original S Grams, all four kernels and least lifts, and the projections directly from $L_{H_i}^{-1} L^{*} H_j$, independently of the monic-basis implementation. It verified the extremizer (F.18), all six trace powers, and the four $p=2$ certificates. A separate 1,024-term rational logarithm series without range reduction produced intervals contained in every audited saved logarithm/certificate interval. Every stdout/stderr hash, Windows CRLF reconstruction, unique check label, complete job count, return code, and ordinary/optimized equality matched; all 88 driver provenance checks passed. These 170 audit predicates remain separate from the fixture's 303 mathematical checks. The reviewer wrote no files.

Final executable SHA256: 88bcee664a3812dd914e5d164de37d48f4388307e2359062ace360e988d9df14.

Final replay JSON SHA256: a8205b83417feb94baf903f53f9bdd0d2e38cf325fc28ceaac6a098530b4075d.

Assigned work, verbatim

New bounded independent task while I derive restriction-AU join: read full work/arithmetic_volume_upper_route_20260913.tex and new restriction full NOTE once intake path available (ask root/arithmetic_endpoint_intake). Construct meaningful exact rational fixtures validating two-pair restriction $T=KiGj$, projection, spectral trace finite upper certificate, explicit remainder-comparator g_0 for $(q-1, 2q-1), (q, 2q)$, retaining literal source mass. Prefer existing EW auxiliary source $S=1+iu$ $\chi=S^2-2S-1$, mass9/16, or actual new Gaussian nilpotent mass7. Do full derivation of finite g_0 from exact polynomial remainder norm and source lower form, and compare bound's gap and trace certificate. Send formulas early; only new work/endpoint_restriction_join_fixture_20260913.{py,md,json} files. Full exact output, actual complete mutations not assertions, independent ordinary+optimized if apt. No edits to frozen files, no Lean or publication. Do not assume a uniform gap.

The selected source is the first explicit option. The parent received early exact comparator and spectral formulas, followed by the replay counts and upper-bound comparison. Existing frozen files, inherited intake checks, Lean calculations, and publication are outside this independent lane and were not changed.

S38 SGA trace, the retained diagonal, and the arithmetic period determinant

Source role. Complete delivered proof note, equations 1-62 including 21a, 28a and 54a-54c; apply the separately recorded visible coefficient-ring and primary-scope corrections. Original display tags retain their complete literal source tokens; the local typesetting namespace SGA identifies this source. The supplied inline metric paragraph after equation50 has a recorded Markdown/TeX embedding defect; SGAC7 gives its complete correctly typed sentence and maps. Its single bare tilde command and exact following G_N argument are rendered inside math delimiters with the original raw payload unchanged and the complete original syntax tree recoverable.

SGA trace, the retained diagonal, and the arithmetic period determinant

S38.1 1. The completed calculation and its role

This continuation uses the **actual inline text in the supplied SGA 5 master**, especially Exposé III, §6.8, together with the preceding polynomial-exponential construction. It calculates, rather than postulates, the relative duality and diagonal class of the current cyclic arithmetic module. That class then evaluates the determinant of the entire exponential period matrix.

The principal formulas are

$$\mathrm{Tr}_{E_t/R}(M_P) = \mathrm{res}_{\chi-t}(\chi'P), \quad \det \Pi(\mathbf{c}, u, t) = \det \Pi_{\mathrm{mon}}(u) \exp\left(\frac{\mathcal{F}(\mathbf{c}, t)}{u}\right), \quad (\text{SGA } 1)$$

where every symbol and map is specified below. In particular,

$$\mathcal{F}(\mathbf{c}, t) = \mathrm{Tr}_{E_t/\mathbb{C}}(M_{\Phi_t}), \quad \det(\Pi^*\Pi) = (2\pi|u|)^q \exp\left(2\Re\frac{\mathcal{F}(\mathbf{c}, t)}{u}\right). \quad (\text{SGA } 2)$$

This evaluates a previously unspecified analytic determinant. Its coefficient derivatives recover **all the first q power traces of the original companion operator**, and hence its whole characteristic polynomial, including multiplicities. The original theta metric is not changed. Its comparison with this calculated determinant is carried through in §§10–12.

These are explicit applications and extensions of classical residue/trace and irregular-period methods; no global priority claim is made. SGA 5 supplies the residue/trace operation, not a Hermitian positivity theorem for the theta quotient. Bloch–Esnault study determinants and periods for irregular connections, including the $\exp(f)$ case; their abstract was inspected, but their full article was not successfully retrieved in this execution. The proof here is supplied in full at the types used here.

S38.2 2. Source intake and mathematical categories

The nine uploaded files are LaTeX masters. SGA 5 contains 15,818 lines of substantive inline material. The other masters have differing amounts of inline material and refer to further component files; for example the SGA 4½ master consists of its preamble and eight component inputs. The absent component contents are not counted as read. SOURCE_REVIEW.md and checks/source-inventory.json give the exact reading and dependency inventory.

The key supplied statement is SGA 5, Exposé III, (6.8.5): the residue of a function multiplied by the regular-immersion class equals the trace of its multiplication endomorphism on a finite flat algebra. The preceding paragraph constructs the class from the conormal differential. The source explicitly records a qualification about the proof/reference of this compatibility. We retain that qualification and prove its one-variable instance directly below.

The appendix works with coherent complexes over a noetherian scheme, with the indicated finite Tor-dimension, properness, and Tor-independence hypotheses. Here the finite map is finite free, so properness and flatness are actual properties of the displayed algebra. Its dual is computed directly as a finite module dual. No general six-operation formalism on semiring schemes is assumed.

Keep the programme's one scalar construction

$$G(R) = \{\tau\} \sqcup \{a^\bullet : a \in R\}, \quad e_R = 0_R^\bullet, \quad p_R(\tau) = 0_R, \quad p_R(a^\bullet) = a. \quad (\text{SGA } 3)$$

Its support observation is $b_R(\tau) = 0$ and $b_R(a^\bullet) = 1$. The pair (p_R, b_R) retains the whole scalar. For every ring map f , its split lift fixes τ and sends $a^\bullet$ to $f(a)^\bullet$. In particular

$$\begin{array}{ccc} G(\mathbb{Z}) & \xrightarrow{G(j)} & G(\mathbb{C}) \\ p_{\mathbb{Z}} \downarrow & & \downarrow p_{\mathbb{C}} \\ \mathbb{Z} & \xrightarrow{j} & \mathbb{C} \end{array} \quad (\text{SGA } 4)$$

remains the original arithmetic square with an infinite left target. All calculations below first specify coefficient maps and then lift them fibrewise through the original support reconstruction. The ordinary coherent realization is connected to that richer object by p , not substituted for the complete split object.

At a label ℓ , an R -linear map f lifts as $(\ell, x) \mapsto (\ell, f(x))$; a coefficient zero remains $(\ell, 0)$. External absence maps to absence. Kernels and quotients below are the original coefficient kernels and quotients before that reconstruction. No new scalar zero is adjoined for a diagonal homology degree or a deformation parameter.

S38.3 3. The arithmetic object that is retained

Fix the original finite packet h , with complete orders, and tensor degree k . Retain

$$g = 2\xi, \quad v_h = g/h, \quad \mathcal{M}F_h = v_h, \quad E = \mathbb{C}[S]/(\chi), \quad A = M_S, \quad \chi = \chi_{h,k}, \quad q = \deg \chi > 0. \quad (\text{SGA } 5)$$

The source and actual weighted inclusion are

$$\mathcal{V}P = P(D_1 + \cdots + D_k)F_h^{\otimes k}, \quad \eta[P] = v_h^{\otimes k} P(A_k)1, \quad v_h = j_h(g/h). \quad (\text{SGA } 6)$$

The retained source identities are

$$J^{(k)}\mathcal{V} = \eta\pi_\chi, \quad q^{(k)}\mathcal{V} = \sigma_h^{\otimes k} \eta\pi_\chi. \quad (\text{SGA } 7)$$

The original scalar measure is

$$w_h(y) = \frac{|v_h(1/2 + iy)|^2}{2\pi}, \quad m_{h,k} = w_h^{*k}, \quad \int m_{h,k} = \mu_h^k, \quad (\text{SGA } 8)$$

and the norm is

$$\|\mathcal{V}P\|^2 = \int_{\mathbb{R}} |P(k/2 + iy)|^2 m_{h,k}(y) dy. \quad (\text{SGA } 9)$$

For $N \geq q - 1$, the canonical matrix and source section remain

$$K_N = B_N O_N^{-1} B_N^*, \quad G_N = K_N^{-1}, \quad R_N = O_N^{-1} B_N^* G_N, \quad V_N = \det G_N. \quad (\text{SGA } 10)$$

Write $r_N = \mathcal{V}R_N$. The established cyclic retraction composed with the full jet map gives j_E on the stated test-function domain, with $j_E r_N = 1$ and $j_E D^{(k)} = A j_E$. The source relation is

$$D^{(k)}r_N - r_N A = dK_N^{\text{prim}}. \quad (\text{SGA } 11)$$

These are inherited interfaces, not analytic theorems re-proved by the finite tests of this note. The empty packet $E=0$ has the empty determinant one; all q -positive constructions below concern $q>0$.

S38.4 4. SGA 5's relative duality, calculated on this polynomial algebra

Let R be a commutative ring, let χ be monic of degree q , and put

$$H(S) = \chi(S) - t, \quad E_t = R[t, S]/(H), \quad f : \text{Spec } E_t \longrightarrow \text{Spec } R[t]. \quad (\text{SGA } 12)$$

The basis $1, S, \dots, S^{q-1}$ proves f finite free of degree q . Set

$$\lambda_t([P]) = [S^{q-1}] \text{rem}_H P. \quad (\text{SGA } 13)$$

Here $[S^{q-1}]$ means coefficient extraction in the actual monic remainder. Over $\mathbb{C}$ it equals the sum of finite residues of $P(S)dS/H(S)$, with the positive finite-residue orientation. Equivalently it is the coefficient of S^{q-1} in P/H , which is the negative of the residue at infinity.

The bilinear form

$$\beta_t(x, y) = \lambda_t(xy), \quad \beta_t^b : E_t \longrightarrow \text{Hom}_{R[t]}(E_t, R[t]) \quad (\text{SGA } 14)$$

is perfect. Its Gram in the unchanged power basis has zeros below total exponent $q-1$ and ones on that antidiagonal. Thus

$$\det \beta_t = (-1)^{q(q-1)/2}. \quad (\text{SGA } 15)$$

This proves perfection over the original coefficient ring, without dividing by a discriminant. The finite duality functor is

$$f^! R[t] = \text{Hom}_{R[t]}(E_t, R[t]), \quad (\text{SGA } 16)$$

in degree zero. Equation (14) is its explicit trivialization; evaluation at 1 is its counit. The factor dS/H and the conormal generator $[H]$ account for the smooth dimension-one and regular codimension-one shifts, which cancel in this finite relative dimension-zero calculation.

S38.4.1 4.1 The actual diagonal class

In $B_t = E_t \otimes_{R[t]} E_t$, with coordinates X, Y , define

$$\mathcal{C}_H(X, Y) = \frac{H(X) - H(Y)}{X - Y} = \sum_{n=1}^q c_n \sum_{a=0}^{n-1} X^{n-1-a} Y^a, \quad c_q = 1. \quad (\text{SGA } 17)$$

The fraction denotes polynomial division with zero remainder; there is no localization at $X-Y$. Its defining identities are

$$(X - Y)\mathcal{C}_H = 0 \text{ in } B_t, \quad \mu(\mathcal{C}_H) = \chi'(S), \quad (\text{SGA } 18)$$

where μ is multiplication $E_t \otimes E_t \rightarrow E_t$.

The first identity shows the class is supported on the diagonal. Moreover

$$(\lambda_t \otimes 1)((P \otimes 1)\mathcal{C}_H) = P \text{ in } E_t. \quad (\text{SGA } 19)$$

To prove it, first take $P=1$: the coefficient of X^{q-1} in (17) is 1. The identity $(X-Y)\mathcal{C}_H=0$ then gives $(P(X)-P(Y))\mathcal{C}_H=0$ for every polynomial P , proving (19). This also proves that $\mathcal{C}_H$ is the coevaluation tensor inverse to (14).

Taking the categorical trace of multiplication gives the complete composite

$$R[t] \xrightarrow{1 \mapsto C_H} E_t \otimes E_t \xrightarrow{M_P \otimes 1} E_t \otimes E_t \xrightarrow{\mu} E_t \xrightarrow{\lambda_t} R[t]. \quad (\text{SGA } 20)$$

Consequently

$$\boxed{\text{Tr}_{E_t/R[t]} M_P = \lambda_t(\chi' P)}. \quad (\text{SGA } 21)$$

This proves the one-variable instance of the supplied SGA 5 III (6.8.5). In that statement the regular-immersion class is the conormal differential $[H] \mapsto \chi' dS$. Its trace map is exactly (20), not an additional sign-free identification.

The bilinear trace form is connected to the perfect residue form by the exact map

$$\tau_t^b = \beta_t^b \circ M_{\chi'} : E_t \longrightarrow E_t^\vee, \quad \tau_t(x, y) = \text{Tr } M_{xy}, \quad \ker \tau_t^b = \text{ann}_{E_t}(\chi'). \quad (\text{SGA } 21a)$$

This proves the complete radical statement for this finite trace form. At a complex root of multiplicity m its radical has dimension $m-1$; the perfect residue form itself remains nondegenerate. It is not the assertion of positivity for the original sesquilinear Weil form. Their connection is the retained reflection and Jacobian composite (24).

All maps (12)–(21) commute with coefficient base change: their entries are polynomial expressions in the coefficients and monic remainders. For tensor products, the coevaluation is the external product of the displayed tensors; the diagonal Jacobian is the product of the χ_i 's. If the coefficient object is placed in degree k , its supertrace is $(-1)^k$ times (21). No geometric weight is inferred from that cohomological sign.

S38.4.2 4.2 The source's supported relation maps to this same class

At $t=0$, the original sum-direction logarithm operator is

$$\mathcal{L}_k = \frac{1}{k} \sum_i \log x_i, \quad \partial_S^{\text{rel}} = \frac{1}{k} \sum_i \partial_{s_i}, \quad \partial_S^{\text{rel}} S = 1. \quad (\text{SGA } 22)$$

Differentiating the full Mellin amplitude $\mathcal{U}(s)P(S)$, where $\mathcal{U} = \prod [v_h(s_i)]$, gives both $\mathcal{U}P'$ and $(\partial \mathcal{U})P$. Applied to an original relation χP , the latter contains χ and is killed by the original arithmetic quotient. Therefore

$$\boxed{j_E \mathcal{L}_k \mathcal{V}(\chi P) = [\chi' P]_\chi}. \quad (\text{SGA } 23)$$

The arithmetic unit is retained in the map before j_E ; it is removed only by the specified inverse/retraction in j_E . Formula (23) does not differentiate an already-formed scalar e . It differentiates an actual source relation before that relation is sent to its supported quotient zero.

The composition of (23) with λ_0 is the trace (21). More generally, with the original reflection $f^\dagger \text{dagger}_k(S) = \overline{f(k - \overline{\lambda} S)}$,

$$\lambda_0(\chi' f^{\dagger k} P) = \text{Tr}_E M_{f^{\dagger k} P} = \sum_\lambda \ell_\lambda \overline{f(k - \overline{\lambda})} P(\lambda). \quad (\text{SGA } 24)$$

The induced trace in the full arithmetic module still uses η and its retained complement. It is not equated with the cyclic trace without that inclusion and complement.

The conormal lift $C[S]/(\chi^2)$ used to compute (23) maps surjectively to the actual contracted level $C[S]/(\chi_2)$, because $(\chi^2) \subseteq I^2 \cap C[S] = (\chi_2)$. No equality of these ideals is asserted. This keeps the formalization session's correction to higher relation depth.

S38.5 5. The whole derived diagonal is retained

There is a complete explicit resolution behind (18). Put $d=X-Y$ and $b=C_H$. Over B_t it is

$$\cdots \xrightarrow{d} B_t \xrightarrow{b} B_t \xrightarrow{d} B_t \xrightarrow{\mu} E_t \longrightarrow 0. \quad (\text{SGA } 25)$$

Exactness. Work first in $T=(R[t,Y]/(H(Y)))[X]$. Then $B_t=T/(db)$. Both d and b are monic polynomials in X , hence non-zero-divisors in T even when the coefficient algebra has nilpotents. If $da \in (db)$, cancellation of

d in T gives $a \in (b)$. If $ba \in (db)$, cancellation of b gives $a \in (d)$. These are precisely the alternating kernel–image identities in (25); $B_t/(d) = E_t$ supplies the augmentation.

Pullback to the diagonal is tensoring (25) by μ . The two differentials become 0 and multiplication by χ' . It follows that

$$HH_0(E_t/R[t]) = E_t, \quad HH_{2a+1}(E_t/R[t]) = E_t/(\chi'), \quad HH_{2a+2}(E_t/R[t]) = \text{ann}_{E_t}(\chi'), \quad a \geq 0. \quad (\text{SGA } 26)$$

These are module identifications; no multiplication or shuffle structure is silently included. Multiplication by X commutes with every map of (25) and specializes to the original S -action on (26).

At a complex root of multiplicity m , χ' is the product of $m(S-\lambda)^{(m-1)}$ with the actual nonzero local unit. Both positive-degree modules have dimension $m-1$. For $m=1$ they vanish. For $m>1$ the higher classes are retained as distinct cohomological degrees over the same split scalar support.

This is a classical hypersurface calculation performed here on the exact polynomial. It computes the derived diagonal; it does not assert that these HH degrees equal the separately indexed original nullity ladder. The map linking this calculation to that ladder is the shared conormal differential (23), together with the displayed quotient from the original contracted relation levels.

S38.6 6. The preceding exponential family and its exact coefficient connections

Now work over $\mathbb{C}$ and write

$$\chi_{\mathbf{c}}(S) = S^q + \sum_{a=0}^{q-1} c_a S^a, \quad \Phi_t(S) = \frac{S^{q+1}}{q+1} + \sum_{a=0}^{q-1} \frac{c_a S^{a+1}}{a+1} - tS. \quad (\text{SGA } 27)$$

The original polynomial is the marked coefficient value $\mathbf{c} = \mathbf{c}_{h,k}$. None of its coefficients is shifted or rescaled.

The previous two-term coefficient complex is

$$\mathcal{C}_{u,t} = [\mathbb{C}[u, t, S] \xrightarrow{D} \mathbb{C}[u, t, S] dS], \quad D(P) = (uP' + (\chi_{\mathbf{c}} - t)P) dS. \quad (\text{SGA } 28)$$

Its unique degree- $<q$ remainder gives a free degree-one module. At $u=t=0$ it is E . The classical finite algebra and this differential quotient have the explicit coefficient-linear inverse maps

$$\rho_{u,t} : E_t \longrightarrow \mathcal{H}_{u,t}, \quad [P]_H \longmapsto [\text{rem}_H P]_D, \quad \rho_{u,t}^{-1}[Q]_D = [\text{rem}_D Q]_H. \quad (\text{SGA } 28a)$$

Both normal-form operations fix every degree- $<q$ polynomial, proving the inverse laws. The map is a coefficient-module isomorphism, not a declaration that multiplication descends through D . For $u \neq 0$ its connections are

$$\nabla_t = \partial_t - S/u, \quad \nabla_{c_a} = \partial_{c_a} + S^{a+1}/((a+1)u). \quad (\text{SGA } 29)$$

The commutators with D vanish term by term. The quotient is by the linear range of D , not an algebra ideal: $[S(\chi-t)] = -u[1]$. The previous note's source deformation

$$D_t^{(k)} = D^{(k)} + tr_N \mathcal{R} j_E, \quad \mathcal{R}[P] = [S^{q-1}] \text{rem}_{\chi}(P) [1] \quad (\text{SGA } 30)$$

satisfies $j_{ED,t}^{(k)}(k) = A(t)j_E$ and $D_t^{(k)}(k)r_N - r_{NA}(t) = dK_N \wedge^{\text{prim}}$, with $A(t) = A + t\mathcal{R}$. Its original source relation is unchanged.

Let C_a be the degree- $<q$ matrix for reduction of $S^{(a+1)}$ times a representative by D/dS , and let $A(t)$ be the usual companion matrix for $\chi-t$. The period matrix obeys

$$\partial_{c_a} \Pi = \Pi C_a / ((a+1)u), \quad \partial_t \Pi = -\Pi A(t) / u. \quad (\text{SGA } 31)$$

S38.6.1 6.1 The trace of the reduced multiplication is exactly classical

Although C_a need not equal $A(t)^{a+1}$,

$$\boxed{\operatorname{Tr} C_a = \operatorname{Tr} A(t)^{a+1}.} \quad (\text{SGA } 32)$$

Here is the explicit comparison. Reducing S^{b+a+1} , with $0 \leq b \leq q-1$ and $0 \leq a \leq q-1$, starts with degree at most $2q-1$. Every term introduced by the uP' part has degree at most $b+a-q \leq b-1$. Later reductions only lower degree. Thus $C_a - A(t)^{a+1}$ is strictly upper triangular in the fixed increasing-power frame: its row indices are strictly below its column index. Its diagonal entries vanish, proving (32). No u -dependent coefficient is discarded from the full matrix.

S38.7 7. Complete evaluation of the determinant of periods

Set $d=q+1$. Fix $u \neq 0$ and a choice of $\arg u$ on a sector. Retain the rays

$$\theta_j = (\arg u + \pi)/d + 2\pi j/d, \quad \ell_j(r) = r e^{i\theta_j}, \quad r \geq 0, \quad \Gamma_j = -\ell_0 + \ell_j, \quad 1 \leq j \leq q. \quad (\text{SGA } 33)$$

The periods are

$$\Pi_{jb}(\mathbf{c}, u, t) = \int_{\Gamma_j} e^{\Phi_t(S)/u} S^b dS, \quad 0 \leq b < q. \quad (\text{SGA } 34)$$

The leading exponent on each ray is $-r^d/(d|u|)$. Lower-degree terms are uniformly dominated on compact coefficient sets. This proves convergence and all coefficient differentiations in (31). Integrating $D(P)e^{(\Phi_t/u)}$ gives a total derivative whose endpoints at infinity vanish and whose two origin values cancel with the stated orientations.

Define the polynomial

$$\boxed{\mathcal{F}(\mathbf{c}, t) = \operatorname{Tr}_{E_t/\mathbb{C}} M_{\Phi_t} = \lambda_t(\chi' \Phi_t).} \quad (\text{SGA } 35)$$

Both descriptions are finite coefficient calculations. At a complex fibre it is the sum of all critical values $\Phi_t(\lambda)$, counted with the multiplicity of each root of $\chi - t$.

Its gradients are

$$\boxed{\partial_{c_a} \mathcal{F} = \frac{1}{a+1} \operatorname{Tr} A(t)^{a+1}, \quad \partial_t \mathcal{F} = -\operatorname{Tr} A(t).} \quad (\text{SGA } 36)$$

Proof. On the open set of simple roots α_j , differentiate $\sum \Phi_t(\alpha_j)$. The α_j derivatives are multiplied by $\Phi_t'(\alpha_j) = \chi'(\alpha_j) - t = 0$. The remaining terms are exactly (36). Both sides of (36) are polynomials in the coefficients, obtained by companion traces. Their equality on the nonempty simple-root open set proves the polynomial identity everywhere, including all collisions. This extension does not replace the fibres by their reductions: their ranks and traces retain multiplicities.

Equations (31), (32), and Jacobi's determinant derivative give

$$\partial_{c_a}(\det \Pi) = \frac{\partial_{c_a} \mathcal{F}}{u} \det \Pi, \quad \partial_t(\det \Pi) = \frac{\partial_t \mathcal{F}}{u} \det \Pi. \quad (\text{SGA } 37)$$

These determinant equations hold even before invertibility is known, by the adjugate identity. At the monomial member $\mathbf{c}=0, t=0, \mathbb{F}=0$ and direct integration gives

$$(\Pi_{\text{mon}})_{jb} = \frac{(d|u|)^{(b+1)/d}}{d} \Gamma\left(\frac{b+1}{d}\right) e^{i(b+1)\theta_0} (e^{2\pi i j(b+1)/d} - 1). \quad (\text{SGA } 38)$$

The last matrix F_d has Gram $F_d^* F_d = d(I_q + J_q)$, where J_q is the all-ones matrix. Indeed expansion of the finite geometric sums gives diagonal $2d$ and off-diagonal d . Hence $|\det F_d|^2 = d^{q+1}$, in particular it is nonzero.

Along the straight coefficient path from the monomial member to any chosen $(\mathbf{c}, t)$, (37) is a scalar differential equation. Integrating it with its actual initial value proves

$$\det \Pi(\mathbf{c}, u, t) = \det \Pi_{\text{mon}}(u) \exp(\mathcal{F}(\mathbf{c}, t)/u). \quad (\text{SGA } 39)$$

There is no path-dependent logarithm in this equation. In particular the period matrix is invertible for every $u \neq 0$, at repeated as well as simple critical points.

The complete unsquared constant is retained by (38), its determinant, the ray ordering, and the choice of $\arg u$. Taking squared moduli and using the gamma multiplication identity

$$\prod_{l=1}^{d-1} \Gamma(l/d) = (2\pi)^{(d-1)/2} d^{-1/2} \quad (\text{SGA } 40)$$

gives

$$\det(\Pi^* \Pi) = (2\pi|u|)^q \exp(2\Re(\mathcal{F}/u)). \quad (\text{SGA } 41)$$

The factor $(2\pi|u|)^q$ is calculated from (38)–(40); it is not assigned a value by choosing a new basis. Formula (38) remains the authoritative phase-containing version.

This explicitly finishes the determinant calculation for the previously constructed exponential comparison. It is consistent with the classical $\exp(f)$ determinant theory; it is not a claim that the full period matrix, or its arithmetic condition number, is determined by its determinant.

S38.8 8. Recover the complete cyclic spectrum from that determinant family

For $1 \leq r \leq q$, equation (37) gives the logarithmic derivative without choosing a logarithm branch:

$$p_r := ru \frac{\partial_{c_{r-1}} \det \Pi}{\det \Pi} = \text{Tr } A(t)^r. \quad (\text{SGA } 42)$$

Put $d_0=1$ and recursively define

$$d_n = -\frac{1}{n} \sum_{r=1}^n d_{n-r} p_r, \quad 1 \leq n \leq q. \quad (\text{SGA } 43)$$

Then

$$\det(XI - A(t)) = X^q + d_1 X^{q-1} + \cdots + d_q = \chi_{\mathbf{c}}(X) - t. \quad (\text{SGA } 44)$$

Proof. In the formal variable z ,

$$\frac{d}{dz} \log \det(I - zA(t)) = -\text{Tr}(A(t)(I - zA(t))^{-1}) = -\sum_{r \geq 1} p_r z^{r-1}. \quad (\text{SGA } 45)$$

Coefficient extraction gives (43), and the determinant is a degree- q polynomial. Because $A(t)$ is the specified cyclic companion action, its characteristic polynomial is also its minimal polynomial. Thus this recovery retains one complete length- m block at every root of multiplicity m . For a general noncyclic larger arithmetic module, traces do not classify all Jordan blocks; its inclusion η and complementary module stay in the source programme.

The precise map chain is

$$(\mathcal{H}, \nabla_{c_a}) \longrightarrow (\det \mathcal{H}, \det \nabla_{c_a}) \xrightarrow{(42)} (p_1, \dots, p_q) \xrightarrow{(43)} \chi - t. \quad (\text{SGA } 46)$$

Only the full coefficient-family derivatives in (42), not a single determinant value, give the recovery.

S38.9 9. Two explicit calibrations

For $\chi(S)=S-\lambda$,

$$\Phi_t(S) = S^2/2 - (\lambda + t)S, \quad A(t) = \lambda + t, \quad \mathcal{F} = -(\lambda + t)^2/2. \quad (\text{SGA } 47)$$

For $u>0$, with the original contour oriented upwards on $i\mathbb{R}$,

$$\Pi(u, t) = i\sqrt{2\pi u} \exp(-(\lambda + t)^2/(2u)). \quad (\text{SGA } 48)$$

In the ordering (33), $q=1$ gives Γ_1 oriented downwards, so $\Gamma_{\text{up}} = -\Gamma_1$ and the period in (48) is the negative of the sole entry of (34). This is the exact orientation map; the squared determinant is unchanged. The full nonzero λ remains; a cohomological dimension or pure finite-field weight does not set it to a critical-line value.

For $\chi(S)=S^2+c_1S+c_0$,

$$\mathcal{F} = c_1^3/6 - c_1(c_0 - t), \quad \det(\Pi^*\Pi) = (2\pi|u|)^2 \exp\left(2\Re \frac{c_1^3/6 - c_1(c_0 - t)}{u}\right). \quad (\text{SGA } 49)$$

At the discriminant $c_1^2-4(c_0-t)=0$ the formula stays unchanged and the fibre retains its double-root algebra. This is tested symbolically. Independent ray quadrature for small declared complex coefficient fixtures is reported separately, without an interval-certification claim.

S38.10 10. Transport the original metric and control through the same periods

At the actual marked coefficients, use the original arithmetic G_N of (10). On the period-coordinate target define the **transported original metric**

$$\tilde{G}_N = \Pi^{-*} G_N \Pi^{-1}, \quad \Pi^{-*} := (\Pi^{-1})^*. \quad (\text{SGA } 50)$$

The map $\Pi:(E, G_N) \rightarrow (\mathbb{C}^q, \tilde{G}_N)$ is an isometry by this explicit formula, not by an assignment of the original metric to L_q . Conversely $\Pi^* \Pi$ is the Gram for the separately specified coordinate metric L_q , and its comparison operator is $G_N \wedge (-1) \Pi^* \Pi$.

The exact determinant formula is

$$\det \tilde{G}_N = \frac{V_N}{(2\pi|u|)^q} \exp\left(-2\Re \frac{\mathcal{F}}{u}\right). \quad (\text{SGA } 51)$$

At a common (c, u, t) , the complete marked endpoint ratio satisfies

$$\frac{\det \tilde{G}_i}{\det \tilde{G}_j} = \frac{V_i}{V_j}. \quad (\text{SGA } 52)$$

Thus every common period determinant factor in that ratio is now explicitly known and cancels by (51), with no remaining unknown proportionality constant. This identifies exactly which information the period determinant does and does not add to the endpoint estimate.

For fixed $u>0$ and real t , differentiate (50), retaining the original G_N fixed and using $\Pi' = -\Pi A(t)/u$. One obtains

$$u \frac{d}{dt} \tilde{G}_N = \Pi^{-*} (A(t)^* G_N + G_N A(t)) \Pi^{-1}, \quad (\text{SGA } 53)$$

and therefore

$$u \frac{d}{dt} \tilde{G}_N - k \tilde{G}_N = \Pi^{-*} W_N(t) \Pi^{-1}, \quad W_N(t) = A(t)^* G_N + G_N A(t) - k G_N. \quad (\text{SGA } 54)$$

At $t = 0$, $W_N(t)$ is the original arithmetic control. For any vector x , the coordinate change $x = \Pi v$ carries both numerator and denominator of its generalized Rayleigh quotient exactly. Equations (30) and (11) show that the source theta primitive remains the same along this specific t -deformation.

This is a differential-metric reformulation of the same problem. The finite-field pure cohomology of the auxiliary family controls its Frobenius, not automatically the right side of (54). The required relation between those operators has not been supplied by taking a determinant.

S38.10.1 10.1 The constituent period minor detects the arithmetic defect

The full determinant is sensitive to all coefficient derivatives by (42), but along the original t-direction it sees only $\text{Tr } A$. In a reflection-stable arithmetic packet of dimension q , $2\Re \text{Tr } A = kq$. For the full conjugation-stable quartet packet, $\text{Tr } A = kq/2$ exactly. This is already the total weight balance; an off-line pair can retain that same real trace.

The correct retained subobject is an actual A -invariant inclusion $I_F : F \hookrightarrow E$, $AI_F = I_F A_F$. Let $p = \dim F$ and define the **rectangular** period map and its two Grams

$$P_F(t) = \Pi(u, t)I_F : F \longrightarrow \mathbb{C}^q, \quad H_F(t) = P_F(t)^* P_F(t), \quad G_{N,F} = I_F^* G_N I_F. \quad (\text{SGA } 54a)$$

The determinant here is the norm of the actual exterior map $\bigwedge^p P_F$ on $\det F$; no determinant of a rectangular matrix is taken. The domain Gram retains the theta-source inclusion $r_N I_F$ and all its jets. For real t and $u > 0$,

$$P'_F(0) = -P_F(0)A_F/u, \quad \boxed{-u \frac{d}{dt} \log \frac{\det H_F(t)}{\det G_{N,F}} \Big|_{t=0} - kp = 2\Re \text{Tr } A_F - kp.} \quad (\text{SGA } 54b)$$

This follows by differentiating the displayed Gram and taking its trace. It is not a purity assumption on F . For the full positive-real-defect generalized eigenspace $F = E_{>}$, the right side is the exact aggregate $L_{h,k}$ already used by the exterior theorem. Thus the period family has an explicit observable for the original off-line defect, not just for its already-balanced total trace.

The original extension to the other constituents is present as well. Let P be the orthogonal projection in the specified period-coordinate metric onto $\text{im } P_F(0)$. Since $A(t) = A + t\mathcal{R}$,

$$\boxed{(1 - P)P'_F(0) = 0, \quad (1 - P)P''_F(0) = -\frac{1}{u}(1 - P)\Pi(u, 0)\mathcal{R}I_F.} \quad (\text{SGA } 54c)$$

Both identities are direct differentiations. The first derivative is internal to F ; the first possible normal acceleration is the exact rank-at-most-one map on the right. Its kernel, image, and norm remain available. A repeated-root primary subspace is allowed; no eigenspace basis or semisimple replacement is used.

Equations (54a)–(54c) specify the constituent period object that can be estimated next. Formula (41) finishes the full determinant, but does not by itself bound these minor norms or their comparison with $G_{N,F}$. The preceding logarithmic-constituent extension and its coupling subtraction remain the source-specific metric input.

S38.11 11. The source-specific remaining term stays explicit

For the current programme, the original endpoint cost is

$$\mathcal{B}_{h,k} = \log \frac{V_{q-1}V_q}{V_{2q-1}V_{2q}}. \quad (\text{SGA } 55)$$

The preceding logarithmic-constituent calculation already supplies a genuine source upper certificate. For an A -invariant inclusion $I:F \rightarrow E$ and its G_j -orthogonal coefficient lift H_0 of E/F , let $C = G_i - G_j$ and

$$G_{F,0} = I^* G_j I, \quad C_F = I^* C I, \quad D_F = I^* C H_0, \quad Q_0 = H_0^* G_j H_0, \quad C_Q = H_0^* C H_0. \quad (\text{SGA } 56)$$

Put $Q_+ = Q_0 + C_Q$ and

$$\Xi_F = Q_+^{-1} D_F^* (G_{F,0} + C_F)^{-1} D_F. \quad (\text{SGA } 57)$$

That construction proves the exact decomposition

$$\log(V_i/V_j) = \log \frac{\det(G_{F,0} + C_F)}{\det G_{F,0}} + \log \frac{\det Q_+}{\det Q_0} - \sum_{a \geq 1} \frac{\text{Tr}(\Xi_F^a)}{a}. \quad (\text{SGA } 58)$$

These are the source matrices that still require uniform control. Under the coordinate change Π , all inclusions, quotient lifts, metrics and D_F are transported together; (58) retains the same values. A period basis does not eliminate the coupling or the theta mass.

The current GitHub statement retains the already derived off-line-quartet consequence

$$\liminf_{k \rightarrow \infty} \frac{\mathcal{B}_{h,k}}{q_k \log k} \geq 4. \quad (\text{SGA } 59)$$

This note does not establish a contradictory upper estimate. It finishes the diagonal trace and the determinant-period calculation, recovers all cyclic power traces from that determinant family, and gives the exact unchanged theta-metric comparison (51)–(54). The quantitative focus remains a bound on (58), or equivalently on the same original generalized control in (54), rather than another uncomputed determinant or an assumption that local support entails metric purity.

S38.12 12. Relation to Deligne’s finite-field family

The previous construction takes the finitely generated coefficient ring R_0 containing the actual c_a and $1/(q+1)!$, and for a specified finite-field specialization of characteristic $p > q+1$ obtains

$$Y^p - Y = \frac{\Phi_t(S)}{u}, \quad u \neq 0. \quad (\text{SGA } 60)$$

Its infinity chart is the original one: with $w=1/S$,

$$\Phi_t/u = w^{-d}b(w), \quad b(0) = 1/(du), \quad bw^d = 1, \quad x_\infty = wv, \quad \Phi_t/u = x_\infty^{-d}. \quad (\text{SGA } 61)$$

The derivative in v has the specified inverse v/d . This is the retained local model for applying Deligne’s exponential-sum/lissity theorem over $u \neq 0$. The generic polynomial has rank- q degree-one compact cohomology and weight-one Frobenius under those hypotheses. Those are the inherited cited Deligne results, not fresh analytic conclusions of this note.

The maps are the span

$$(R_0, \Phi, u, t) \longrightarrow \begin{cases} (\mathbb{C}, \mathcal{C}_{u,t}, \nabla, \Pi), \\ (\mathbb{F}_Q, \mathcal{L}_\psi(\Phi_t/u), R^1 f_!). \end{cases} \quad (\text{SGA } 62)$$

The SGA trace formalism applies in each specified coefficient realization with its own endomorphism. It does not supply a homomorphism $\mathbb{C} \rightarrow \mathbb{F}_Q$ or an intertwiner from the auxiliary Frobenius to the original A . The actual complex source/operator comparison is (30), (31), and (54). This keeps the two realizations connected at their common coefficient model without filling the missing operator comparison with an unsupported equality.

S38.13 13. Verification and reproducibility

check_trace_period.py contains eighteen finite exact regression methods: residue duality, the diagonal tensor, the trace/Jacobian composite, repeated-root fibres, periodic diagonal resolution, coefficient-base-change identities, quantum-reduction traces, critical-value gradients, Newton recovery, source conormal response, full metric congruences, and split quotient labels. Separate negative controls alter the Jacobian, discard the quantum derivative, or erase multiplicity; each must fail in both normal and optimized Python.

The period convergence, determinant formula for arbitrary q , and all-general resolution exactness have written proofs above. Finite symbolic or numerical tests are not replacements for those proofs. period_num erics.py performs additional explicitly non-certified contour comparisons on declared small fixtures. No new Lean execution, arithmetic zero location, interval certificate, or uniform purity theorem is claimed.

The package does not redistribute the uploaded SGA corpus. The source inventory retains hashes, original paths and read ranges. The GitHub read was pinned to c05c709d707bacda335deff70fbb5b841a751d1f. No remote file is changed by building this package.

S38.14 References and source status

1. A. Grothendieck, written up by L. Illusie, *SGA 5, Exposé III: Lefschetz Formula*, §§4.1, 4.7–4.8, and coherent appendix §§6.1–6.8, especially (6.8.5). Basis: the user’s supplied English master, read directly as LaTeX. Source wording and qualifications are recorded separately.
2. P. Deligne, *La conjecture de Weil II*, Publications Mathématiques de l’IHÉS 52 (1980), 137–252. The previous source-reviewed construction uses §§3.7.2–3.7.4. This execution reads that predecessor’s TeX and preserves its stated scope, rather than claiming a new complete scan verification.
3. S. Bloch and H. Esnault, *Gauß–Manin determinant connections and periods for irregular connections*, arXiv:math/9912095 (1999). The abstract was inspected for attribution; its TeX download failed, so no detailed theorem of that article is asserted as independently read here.
4. NIST Digital Library of Mathematical Functions, §5.5(iii), gamma multiplication formula. It is used only to evaluate the explicit product in (38); the full product and phases remain available.
5. Parent programme sources: *Tau_Deligne_Exponential_Comparison* and *Tau_Deligne_Logarithmic_Constituent_Control*, 13 September 2026. Their original sections, arithmetic source maps, metric definitions, and verification scopes are retained. General source and analytic constructions are inherited where expressly marked above.

S39 The original theta complex inside the Hochschild trace realization

Source role. Complete public PR27 proof note H1-H42, including all source qualifications, critical-kernel maps and the zero-line heat-family proof. Original display tags retain their complete literal source tokens; the local typesetting namespace CC-H identifies this source.

S39.1 The original theta complex inside the Hochschild trace realization

Research continuation, 13 September 2026. Source attribution: the split-support arithmetic programme and its representative maps are the owner's construction. The literature comparison uses Connes and Consani (2023), printed pp. 83–101. This note gives written proofs of the comparison and its boundary qualification. It does not claim a formalization of the adèle crossed product, Schwartz analysis, sheaf cohomology, or a uniform arithmetic weight estimate.

S39.1.1 1. Fix the objects before comparing them

Use the original spaces

$$V = \{\phi \in \mathcal{S}(\mathbb{R})_{\text{ev}} : \phi(0) = 0, \int_{\mathbb{R}} \phi = 0\}, \quad \mathcal{B} = \{F : \sup_{x>0} x^b |D^m F(x)| < \infty \forall b \in \mathbb{Z}, m \geq 0\}, \quad D = -x\partial_x. \quad (\text{CC-H H1})$$

The arithmetic map and its original quotient are

$$\Theta : V \longrightarrow \mathcal{B}, \quad \Theta\phi(x) = 2 \sum_{n \geq 1} \phi(nx), \quad Q = \mathcal{B}/\Theta V. \quad (\text{CC-H H2})$$

The factor two, the quotient topology, and the original supported coefficient square remain

$$\begin{array}{ccc} G(\mathbb{Z}) & \longrightarrow & G(\mathbb{C}) \\ p_{\mathbb{Z}} \downarrow & & \downarrow p_{\mathbb{C}} \\ \mathbb{Z} & \longrightarrow & \mathbb{C}. \end{array} \quad (\text{CC-H H3})$$

Here the supported scalar zero is $e = 0^\bullet$, not the absent scalar τ . Every linear comparison below is a comparison of coefficient fibres; its split lift sends (λ, v) to (λ, fv) , and sends external absence to external absence. In particular an amplitude killed by a comparison remains $(\lambda, 0)$. We do not apply ordinary Hochschild homology directly to the split semiring and assert that additive completion preserves its support masks.

S39.1.2 2. The theta map is the actual Hochschild trace

Let

$$\mathcal{A} = \mathcal{S}(\mathbb{A}_{\mathbb{Q}}) \rtimes \mathbb{Q}^\times, \quad j(f) = [(1_{\mathbb{Z}} \otimes f)U(1)] \in HH_0(\mathcal{A}). \quad (\text{CC-H H4})$$

Connes and Consani, Proposition 3.1, identify the kernel of the inclusion-induced map $\pi_!$ with the span of the differences $f - f^q$. Proposition 3.3 identifies even Schwartz functions with the specified finite-unit-invariant **image of** $\pi_!$. This is not an identification with every sector of $HH_0(\mathcal{A})$.

Their orbit-trace calculation, Lemma 3.2(ii), gives

$$\text{Tr } j(f)(u) = 2 \sum_{n \geq 1} f(nu). \quad (\text{CC-H H5})$$

Consequently the following is a literal factorization of the original arithmetic map:

$$V \xrightarrow{j} HH_0(\mathcal{A}) \xrightarrow{\text{Tr}} \mathcal{B}, \quad \text{Tr} \circ j|_V = \Theta. \quad (\text{CC-H H6})$$

The last arrow in (H6) is understood on the displayed subspace, where its trace has the stated strong-Schwartz range; an unrestricted trace on all crossed-product classes is not asserted.

The book's normalized map is

$$\mathcal{E}f(u) = u^{1/2} \sum_{n \geq 1} f(nu) = \frac{1}{2} \mathcal{U} \Theta f(u), \quad \mathcal{U}F(u) = u^{1/2} F(u). \quad (\text{CC-H H7})$$

The map $\mathcal{U} : L^2(\mathbb{R}_{>0}, du) \rightarrow L^2(\mathbb{R}_{>0}, du/u)$ is an isometry, since its squared norm is exactly $\int |F|^2 du$. This assertion uses the positive half-line. An even full-line realization has its separately retained factor two.

S39.1.3 3. The source Gaussian is exactly a Laplacian preimage

Write the book's generator as $H = x\partial_x = -D$, and distinguish its Laplacian from a representative increment:

$$\mathcal{L} = H(1 + H) = D^2 - D. \quad (\text{CC-H H8})$$

For the unchanged Gaussian $g_0(x) = e^{-\pi x^2}$, direct differentiation gives

$$\boxed{\mathcal{L}g_0 = (4\pi^2 x^4 - 6\pi x^2)e^{-\pi x^2} = \phi_*}. \quad (\text{CC-H H9})$$

Thus the original source function has the exact homological expression

$$f_0 = \Theta\phi_* = \text{Tr } j(\mathcal{L}g_0), \quad \mathcal{M}f_0(s) = 2\xi(s). \quad (\text{CC-H H10})$$

For example, Mellin integration by parts gives

$$\mathcal{M}\phi_*(s) = \frac{1}{2}s(s-1)\pi^{-s/2}\Gamma(s/2), \quad (\text{CC-H H11})$$

initially in a common convergence half-plane and then by continuation. Multiplication by $2\zeta(s)$ gives $2\xi(s)$, not $\xi(s)$. No change of seed or leading coefficient is involved.

Lemma 4.1(iii) of the chapter gives a bijection $\mathcal{L} : \mathcal{S}(\mathbb{R})_{\text{ev}} \rightarrow V$. The differential operator is continuous. The two moment constraints define a closed Frechet subspace, so the open mapping theorem also gives a continuous inverse. We obtain a topological cochain isomorphism

$$[\mathcal{S}(\mathbb{R})_{\text{ev}} \xrightarrow{\Theta\mathcal{L}} \mathcal{B}] \xrightarrow{(\mathcal{L}, 1)} [V \xrightarrow{\Theta} \mathcal{B}]. \quad (\text{CC-H H12})$$

It commutes with the polynomial action of D . Moreover $\mathcal{F}D = (1 - D)\mathcal{F}$, so $\mathcal{F}\mathcal{L} = \mathcal{L}\mathcal{F}$. Hence the same comparison on both ordered legs gives

$$[\mathcal{S}_{\text{ev}}^2 \xrightarrow{\Theta\mathcal{L}(1, -\mathcal{F})} \mathcal{B}] \xrightarrow{(\mathcal{L} \oplus \mathcal{L}, 1)} [V^2 \xrightarrow{\Theta(1, -\mathcal{F})} \mathcal{B}]. \quad (\text{CC-H H13})$$

The degree-zero cycle $(v, \mathcal{F}^{-1}v)$ is transported, not removed. The fibrewise lifts of (H12)–(H13) preserve the original labels and commute with synchronization into the joint label.

S39.1.4 4. Keep the closure comparison as an arrow

The quotient in Proposition 4.2 is, on the specified trace image,

$$Q_{\text{CC}} = \mathcal{B} / \overline{\text{Tr } j(\mathcal{L}\mathcal{S}_{\text{ev}})} = \mathcal{B} / \overline{\Theta V}. \quad (\text{CC-H H14})$$

There is always a canonical continuous map

$$Q \longrightarrow Q_{\text{CC}}, \quad \ker = \overline{\Theta V} / \Theta V. \quad (\text{CC-H H15})$$

Under the prior global-retraction theorem $\Lambda\Theta = 1_V$, the image ΘV is closed: it is the range of the continuous idempotent $\Theta\Lambda$, equivalently the kernel of $1 - \Theta\Lambda$. Then (H15) is a topological isomorphism. This use of the prior analytic theorem is explicit; a finite matrix computation does not prove it.

The chapter's full spectral statement concerns Q_{cc} : the Laplacian eigenvalues are $\rho(\rho - 1)$ for all nontrivial zeros, with their jets. Its critical-only construction later in the chapter is a different quotient. The following calculation supplies a map between the two kinds of coefficient object without presuming injectivity.

S39.1.5 5. A specified critical-line comparison and its exact finite kernel

Choose the plus-sign Mellin restriction

$$J_{\text{crit}} : \mathcal{B} \longrightarrow \mathcal{S}(\mathbb{R}), \quad J_{\text{crit}} F(t) = \mathcal{M}F(\tfrac{1}{2} + it). \quad (\text{CC-H H16})$$

This is continuous: in logarithmic coordinates, $e^{y/2}F(e^y)$ and all derivatives have faster-than-polynomial decay, with bounds controlled by finitely many defining seminorms of $\mathcal{B}$. Fourier transformation therefore lands continuously in Schwartz space. The plus sign is deliberate; the chapter's displayed Fourier transform uses the opposite sign, related by $t \mapsto -t$.

Put

$$z_c(t) = \zeta(\tfrac{1}{2} + it), \quad Q_{\text{crit}} = \mathcal{S}(\mathbb{R}) / \overline{z_c \mathcal{S}(\mathbb{R})}. \quad (\text{CC-H H17})$$

For $\phi \in V$, Mellin factorization gives

$$J_{\text{crit}}(\Theta\phi)(t) = 2z_c(t)\mathcal{M}\phi(\tfrac{1}{2} + it). \quad (\text{CC-H H18})$$

The remaining Mellin factor is Schwartz: at the origin $\phi(u) = O(u^2)$, and at infinity it is Schwartz; repeated logarithmic differentiation and integration by parts control every Fourier seminorm. The zeta factor is a Schwartz multiplier, as used in the chapter's Section 5. Thus (H18) induces an actual continuous linear map

$$\boxed{\Gamma : Q \longrightarrow Q_{\text{crit}}, \quad [F] \longmapsto [J_{\text{crit}}F].} \quad (\text{CC-H H19})$$

It also factors through (H15), by continuity and the closed target relation space. Its operator equations are

$$\Gamma D_Q = M_{1/2+it}\Gamma, \quad \Gamma(a^{-1/2}\overline{U}_a) = M_{a^{it}}\Gamma. \quad (\text{CC-H H20})$$

Theorem 5.4 identifies the target coefficient quotient with global sections of the Scaling Site quotient sheaf. Section 7 below records a zero-mode qualification needed before using the printed raw-section formula at the boundary $L = 0$.

Now let Z be a finite packet of actual zeros, with the retained multiplicities, and use the previously constructed inclusion

$$\sigma_Z : E_Z = \mathbb{C}[s]/(h_Z) \hookrightarrow Q, \quad D_Q\sigma_Z = \sigma_Z A_Z, \quad A_Z = M_s. \quad (\text{CC-H H21})$$

Chinese remainders give the specified decomposition $E_Z = E_{Z,\text{crit}} \oplus E_{Z,\text{off}}$, according to whether $\Re\rho = 1/2$. Then

$$\boxed{\ker(\Gamma\sigma_Z) = E_{Z,\text{off}}.} \quad (\text{CC-H H22})$$

Proof on the off-critical blocks. For $\Re\rho \neq 1/2$, the function $(1/2 + it - \rho)^{-1}$ is smooth on the real line and all its derivatives are polynomially bounded. It is a continuous Schwartz multiplier, commutes with z_c , and preserves both the ideal and its closure. Therefore $M_{1/2+it} - \rho$ is invertible on Q_{crit} . If $(A_Z - \rho)^m v = 0$, (H20) gives

$$(M_{1/2+it} - \rho)^m \Gamma\sigma_Z v = 0,$$

and hence $\Gamma\sigma_Z v = 0$. This kills the full generalized block under this particular map, not just its reduced eigenline.

Proof on a critical block. Let $\rho = 1/2 + i\gamma$ have order m . The continuous derivative evaluations descend to

$$\Xi_\rho : Q_{\text{crit}} \longrightarrow \mathbb{C}[\epsilon]/(\epsilon^m), \quad \Xi_\rho[f] = \sum_{j=0}^{m-1} \frac{i-j}{j!} f^{(j)}(\gamma) \epsilon^j. \quad (\text{CC-H H23})$$

Indeed these functionals vanish on $z_c \mathcal{S}$, and hence on its closure. The chain rule gives

$$\Xi_\rho \Gamma[F] = \sum_{j < m} \frac{(\mathcal{M}F)^{(j)}(\rho)}{j!} \epsilon^j. \quad (\text{CC-H H24})$$

The right side is exactly the original Mellin-jet observation. Its composite with σ_Z is the Chinese-remainder projection to the ρ -block, by $J_Z \sigma_Z = 1$. Taking all critical blocks provides a left inverse on $E_{Z,\text{crit}}$, proving (H22).

In split coordinates, (H22) says

$$\tilde{\Gamma}(\lambda, \sigma_Z v) = (\lambda, 0) \quad (v \in E_{Z,\text{off}}), \quad (\text{CC-H H25})$$

not external absence. The critical quotient's spectral location does not establish injectivity of (H19). Formula (H22) calculates the exact finite failure of injectivity that a comparison argument would have to address.

S39.1.6 6. The original metric supplies the Laplacian defect, not an assumed Hodge star

Fix an original representative $R : E_Z \rightarrow \mathcal{B}$ with

$$DR - RA = \Theta K, \quad G = R^* R, \quad W = A^* G + GA - G. \quad (\text{CC-H H26})$$

The normalized representative $\hat{R} = \mathcal{U}R$ has the same Gram matrix. With $D_\times = -u\partial_u$ acting in multiplicative coordinates,

$$D_\times \hat{R} - \hat{R}(A - \tfrac{1}{2}I) = \mathcal{U}\Theta K = 2\mathcal{E}K, \quad W = (A - \tfrac{1}{2}I)^* G + G(A - \tfrac{1}{2}I). \quad (\text{CC-H H27})$$

Thus the shift and the source boundary are both accounted for. In particular applying $\mathcal{U}$ to the entire relation curve $R_j + z\delta R$ leaves its Gram matrix, restriction return, determinant ratio, and curvature cost unchanged.

For the tensor-weight algebraic formula, let $k \in \mathbb{R}$, keep the original A, G , and put

$$L_k = A^2 - kA, \quad W_k = A^* G + GA - kG. \quad (\text{CC-H H28})$$

Expansion proves

$$\boxed{L_k^* G - GL_k = A^* W_k - W_k A}, \quad \boxed{GL_k = W_k A - A^* G A}. \quad (\text{CC-H H29})$$

Writing $B = A - kI/2$ gives the equivalent centered energy identity

$$\boxed{GL_k = W_k B - B^* G B - \frac{k^2}{4} G}. \quad (\text{CC-H H30})$$

For (H29), expand $A^*(A^*G + GA - kG) - (A^*G + GA - kG)A$; the middle A^*GA terms cancel and the remaining expression is $L_k^* G - GL_k$. For (H30), substitute $GA = W_k - A^*G + kG$, or expand with $A = B + kI/2$. These are exact identities before any estimate. The real part of the first term on the right of (H30) is the retained error in the expected negative energy inequality.

The existing rank-two source formula for W_n consequently gives a rank-at-most-four formula for $L^*G - GL$. This rank fact alone bounds neither its relative norm nor its effect on the growing arithmetic packet.

An actual constituent inclusion J with $AJ = JA_F$ satisfies $L_k J = J(A_F^2 - kA_F)$. No commutation of A with a metric restriction-loss operator is required.

The full jet formula is

$$L_k|_{E_\rho} = \rho(\rho - k)I + (2\rho - k)N_\rho + N_\rho^2. \quad (\text{CC-H H31})$$

When $2\rho - k \neq 0$, the nilpotent factor $(2\rho - k)I + N_\rho$ is invertible and commutes with N_ρ . Therefore the powers of the nilpotent part have exactly the same kernels as N_ρ^j : Jordan lengths remain unchanged. In particular negative real diagonal spectrum is not the same as self-adjointness on a positive Hilbert metric. Requiring exact self-adjointness on a multiple-zero packet would also force semisimplicity. The chapter itself retains nontrivial Jordan actions in Remark 5.5.

S39.1.7 7. The boundary zero mode needs to be retained separately

There is a concrete qualification in the printed Section 5 construction. Proposition 5.2(iii), p. 94, places the raw family $\Sigma_{eL}\mathcal{E}\phi$ in the smooth-section sheaf vanishing at $L = 0$. But the same proof, p. 95, explicitly gives its zeroth normalized Fourier coefficient as

$$\widehat{\Sigma_{eL}\mathcal{E}\phi}(0) = L^{-1/2}a_\phi, \quad a_\phi = \int_0^\infty \mathcal{E}\phi(u) \frac{du}{u} = \zeta(\tfrac{1}{2})\mathcal{M}\phi(\tfrac{1}{2}). \quad (\text{CC-H H32})$$

For the original seed (H9) this is

$$a_{\phi_*} = \xi(\tfrac{1}{2}) \neq 0. \quad (\text{CC-H H33})$$

The nonvanishing is exact, not inferred from numerics. In (H11) the gamma factor is nonzero at $1/2$; and $\zeta(s) = \eta(s)/(1 - 2^{1-s}) < 0$ for real $0 < s < 1$, since the paired alternating series for $\eta(s)$ is strictly positive. Thus the raw coefficient $\xi(1/2)L^{-1/2}$ does not extend continuously to zero, let alone vanish to all orders. This calculation concerns the literal raw-section assertion, not the validity of the preceding Hochschild trace and all-zero quotient statements.

A support-retaining repair is to use the augmented Fourier-coordinate object

$$\mathcal{H}^\#(U) = C_{\text{flat}}^\infty(U, \ell^2(\mathbb{Z} \setminus \{0\})) \oplus C^\infty(U), \quad (\text{CC-H H34})$$

where flatness is imposed at zero when it belongs to U . Map a source function to

$$\Sigma^\# \mathcal{E}\phi = (\Pi_{\neq 0} \widehat{\Sigma \mathcal{E}\phi}, a_\phi). \quad (\text{CC-H H35})$$

For $L > 0$, reconstruct the full raw Fourier vector by

$$(\eta(L), a(L)) \mapsto \eta(L) + L^{-1/2}a(L)e_0. \quad (\text{CC-H H36})$$

In the circle's function coordinates, the added constant function has value $a(L)/L$. The different powers in these two coordinate systems are forced by the unitary normalization of the Fourier basis.

The covering transfer satisfies

$$\widehat{\sigma_n \xi}(L, j) = \sqrt{n} \widehat{\xi}(nL, nj). \quad (\text{CC-H H37})$$

Accordingly the renormalized zero-line coordinate transforms by $a(L) \mapsto a(nL)$. The two components in (H34) therefore have genuine compatible $\mathbb{N}^\times$ -actions. Normalized scaling is trivial on the zero line. Nothing has been silently discarded.

The extra zero line is an actual closed boundary Here is an explicit source proof of its fate in the quotient. For $T > 0$, form in the original Frechet space

$$\phi_T(x) = \frac{1}{\sqrt{4\pi T}} \int_{\mathbb{R}} e^{-r^2/(4T)} e^{-r/2} \phi_*(e^{-r}x) dr. \quad (\text{CC-H H38})$$

For every fixed Schwartz seminorm the seminorm of the integrand's dilated factor is bounded by a constant times $e^{C|r|}$. Hence the Gaussian integral converges in Schwartz space. Parity and both original moment conditions persist, so $\phi_T \in V$. This does not assert uniform source seminorm bounds as $T \rightarrow \infty$.

The normalized dilation identity

$$\mathcal{E}(e^{-r/2}\phi_*(e^{-r}\cdot))(u) = \mathcal{E}\phi_*(e^{-r}u)$$

and Fourier transformation give

$$\widehat{\mathcal{E}\phi_T}(s) = e^{-Ts^2}\widehat{\mathcal{E}\phi_*}(s), \quad a_{\phi_T} = a_{\phi_*}. \quad (\text{CC-H H39})$$

On every compact interval $0 \leq L \leq M$, all nonzero frequencies have magnitude at least $2\pi/M$. Differentiating their Fourier coefficients produces only finite sums of powers of T , frequency, and L^{-1} , times the Gaussian and derivatives of a Schwartz function. Splitting the Gaussian into two equal factors yields, for each flat-section seminorm of derivative order m , a bound

$$p_{N,m,[0,M]}(\Pi_{\neq 0}\widehat{\Sigma\mathcal{E}\phi_T}) \leq C_{N,m,M}(1+T)^m e^{-2\pi^2 T/M^2} \longrightarrow 0 \quad (T \geq 1). \quad (\text{CC-H H40})$$

To see the uniformity at $L = 0$, replace every negative power of L by a corresponding power of $|s|/(2\pi|n|)$, use the second Gaussian to absorb frequency powers, and sum an arbitrarily high negative power of $|n|$. The required constants depend on finitely many Schwartz seminorms of $\widehat{\mathcal{E}\phi_*}$.

Thus

$$\Sigma^\# \mathcal{E}\phi_T \longrightarrow (0, \xi(1/2)). \quad (\text{CC-H H41})$$

Since the last scalar is nonzero, the closed source-generated module in (H34) contains the entire renormalized zero line. Multiplication by local smooth functions gives the corresponding sheaf statement. Once this line is retained, its removal from the quotient is justified by a displayed family of original source relations. Algebraically, if $N \subset M \oplus \mathcal{O}$ is the closed source module and $0 \oplus \mathcal{O} \subset N$, then $N = \text{pr}_M \bar{N} \oplus \mathcal{O}$, and the quotient is the nonzero-mode quotient. The split lift makes the zero line a supported boundary, not absence.

This is a written repair and comparison, not a completed Lean proof of the heat-limit or sheaf assertion. It supplies the missing zero-mode convention without adding an artificial third vanishing condition to the original V .

A separate local typo on p. 100 is also relevant when reading the quotient argument: $\zeta(1/2 \mp 2\pi i/L)$ tends to $\zeta(1/2) \neq 0$ as $L \rightarrow \infty$, not as $L \rightarrow 0$. We use the former limit. The published page and the supplied scan were inspected; this is not an OCR substitution.

S39.1.8 8. What has and has not been identified

The established chain is

$$\text{original theta source} \xleftarrow{\mathcal{L}} \text{specified Hochschild trace image} \longrightarrow Q_{\text{CC}} \xrightarrow{\Gamma} Q_{\text{crit}}, \quad (\text{CC-H H42})$$

where the first comparison is the actual two-term-complex isomorphism (H12), not a degree-forgetting isomorphism of every displayed space. On finite arithmetic packets the last arrow has the calculated kernel (H22), and every surviving critical jet has the explicit recovery (H23).

The polynomial Laplacian uses the actual arithmetic action A . The curvature restriction-loss operator uses the actual source metrics. They are not identified with one another, and their eigenspaces are not presumed to agree. Equations (H27)–(H31) give the actual connection through the original boundary form W .

The chapter's Hodge dictionary is explicitly heuristic on p. 91. Its Corollary 4.3 makes a negative-spectrum statement equivalent to RH; it does not prove that statement by declaring the displayed star to be the adjoint for the original Gram metric. Here (H29) computes that adjoint defect instead.

S39.1.9 9. Formal and computational scope

SplitZeroLaplacianControl.lean formalizes the matrix identities (H29), constituent intertwining, the full quadratic jet (H31), and the general lemma that an intertwiner sends a nilpotent block to zero when the corresponding shifted target operator is injective. The actual target multiplier's invertibility and the critical-jet recovery are the analytic written proof in Section 5, not assumed custom Lean axioms.

The four preceding new modules formalize the relation Gram curve, polynomial local specialization sequence, least invariant hull, and curvature/restriction scalar identities. Their scope and the cyclic gcd/metric-pole consequences are recorded in RESEARCH_NOTE.md. The strict workflow checks individual sources at `--trust=0`, treats warnings as errors, and audits the selected 29+9 new declarations against `propext`, `Classical.choice`, and `Quot.sound`. Actual run status is recorded separately after execution; source text alone is not a successful certificate.

The exact Python checks include the original Gaussian differentiation, all factors in (H11), the non-Euclidean polynomial-source Gram metric, generalized jets, the derivative phase $i^{-j}/j!$, and the renormalized covering coefficient. The finite critical/off-critical polynomial calibration is expressly not a set of asserted zeta zeros. Neither those checks nor the Lean algebra prove a uniform arithmetic nonconcentration bound.

S39.1.10 References and reading scope

S40.1 A quantitative Laplacian bound from the original control form

13 September 2026. This is a written consequence of the source-preserving identities in HOCHSCHILD_COMPARISON.md, equations (H29)–(H30). It concerns the original Gram metric and does not require diagonalizability. The scalar enclosure below is not included in the selected Lean audit of this package.

Let $G \succ 0$, $k \in \mathbb{R}$, and let the actual arithmetic action be A . Set

$$B = A - \frac{k}{2}I, \quad W = A^*G + GA - kG, \quad L = A^2 - kA. \quad (\text{CC-P P1})$$

Suppose a verified two-sided control is available on that same metric:

$$-\varepsilon G \preceq W \preceq \varepsilon G, \quad \varepsilon \geq 0. \quad (\text{CC-P P2})$$

The source's rank-two formula supplies an explicit way to evaluate the least such ε ; (P2) is not asserted to be uniformly small on growing arithmetic packets.

S40.1.1 Numerical-range enclosure

For every $v \neq 0$, put $z = \langle v, Lv \rangle_G / \|v\|_G^2$. Then

$$\Re z \leq \frac{\varepsilon^2 - k^2}{4}, \quad (\Im z)^2 \leq \varepsilon^2 \left(\frac{\varepsilon^2 - k^2}{4} - \Re z \right). \quad (\text{CC-P P3})$$

In particular every eigenvalue of L lies in the displayed closed left-facing parabola. This is stronger than a statement only about the eigenvalues: it controls the entire numerical range in the original G -inner product.

Proof. Normalize $\|v\|_G = 1$, put $r = \|Bv\|_G$, and define

$$a + ib = \langle v, G^{-1}WBv \rangle_G. \quad (\text{CC-P P4})$$

The operator $G^{-1}W$ is self-adjoint in the G -metric, and (P2) bounds its operator norm by ε . Cauchy-Schwarz gives

$$a^2 + b^2 \leq \varepsilon^2 r^2. \quad (\text{CC-P P5})$$

The exact energy identity $GL = WB - B^*GB - k^2G/4$ gives

$$x := \Re z = a - r^2 - k^2/4, \quad \Im z = b. \quad (\text{CC-P P6})$$

First $a \leq \varepsilon r$, and completing the square proves

$$x \leq \varepsilon r - r^2 - k^2/4 = \frac{\varepsilon^2 - k^2}{4} - (r - \varepsilon/2)^2. \quad (\text{CC-P P7})$$

For the second assertion, compute without discarding the cross term:

$$\varepsilon^2 \left(\frac{\varepsilon^2 - k^2}{4} - x \right) - b^2 = (a - \varepsilon^2/2)^2 + \varepsilon^2 r^2 - a^2 - b^2 \geq 0. \quad (\text{CC-P P8})$$

This proves both assertions, including $\varepsilon = 0$. No spectral simplicity, Euclidean normality, or commutation with the restriction-loss matrix is used.

S40.1.2 What it says about the Connes–Consani comparison

At weight one, the chapter’s arithmetic Laplacian acts as $A(A - I)$. Formula (P3) therefore turns a source-level rank-two control certificate into a quantitative spectral enclosure for that Laplacian. The positivity and adjoint belong to the original $G = R^*R$, whose failure to be invariant was calculated rather than assumed away.

If $0 < \varepsilon < |k|$, the numerical range has strictly negative **real part**. This does not make its spectrum real; it is not the negative-real-spectrum conclusion in Connes and Consani’s Corollary 4.3. At a finite positive error, the parabola retains non-real possibilities.

For a repeated block $A = \rho I + N$, the action remains $L = \rho(\rho - k)I + (2\rho - k)N + N^2$. Nothing in the proof deletes the nilpotent term. An exact positive self-adjoint realization on a full multiple-zero block would impose extra semisimplicity; (P3) avoids making that assumption.

For an actual tensor tower with action containing the character $k\rho$, division by k^2 gives the same enclosure for the fixed scalar $\rho(\rho - 1)$, with error ratio ε_k/k . A separately proved limit $\varepsilon_k/k \rightarrow 0$ would collapse these enclosures to the negative real half-line. This records a precise quantitative contract for the original tower; the limit is not proved by the enclosure itself.

S41.1 Specialization, invariant hulls, and the original curvature cost

13 September 2026. This note continues the owner's supplied specialization/curvature construction and the verified restriction work of PR26. It records the written geometric consequences and the precise scope of the four new coefficient-level Lean modules. The companion HOCHSCHILD_COMPARISON.md uses the newly supplied Connes–Consani chapter without replacing these source metrics.

S41.1.1 1. Source and finite observation

Fix one of the original blocks $i < j$, its full quotient $E = \mathbb{C}[S]/(\chi)$, and its original action $A = M_S$. Work in the specified polynomial-source coordinates, with positive Gram matrix O_j . Pad the earlier representative into the later source and call it X . Keep

$$B_j X = B_j R_j = 1_E, \quad G_i = X^* O_j X, \quad R_j^* O_j = G_j B_j. \quad (\text{CC-S S1})$$

Put $\delta R = X - R_j$. The original observation gives $B_j \delta R = 0$, while the dual equation gives

$$R_j^* O_j \delta R = 0, \quad C := \delta R^* O_j \delta R = G_i - G_j \succeq 0. \quad (\text{CC-S S2})$$

For $R(z) = R_j + z \delta R$, expansion therefore yields

$$B_j R(z) = 1_E, \quad R(z)^* O_j R(z) = G_j + |z|^2 C. \quad (\text{CC-S S3})$$

The original action defect obeys

$$W(z) = A^* G(z) + G(z) A - k G(z) = W_j + |z|^2 (W_i - W_j). \quad (\text{CC-S S4})$$

All of (S2)–(S4) are composed with the previously verified relation-Gram theorem in SplitZeroRelationCurve.lean. A specified constituent $I_F : F \rightarrow E$ is carried by $R(z)I_F$, not by an unrelated spectral model.

S41.1.2 2. The actual local equation and the derived fibre

Let $E_0 = \ker \delta R$ and let E_1 be its G_j -orthogonal complement. Write P_0, P_1 for these projections and $r = \dim E_1 = \text{rank } C$. The source bundle on $\mathbb{P}^1$ is

$$\mathcal{M} = (E_0 \otimes \mathcal{O}) \oplus (E_1 \otimes \mathcal{O}(-1)). \quad (\text{CC-S S5})$$

On the infinity chart $w = 1/z$, its inclusion into the trivial quotient bundle is

$$\alpha(w) = P_0 + w P_1. \quad (\text{CC-S S6})$$

The polynomial local presentation is not merely a pointwise matrix: on free coefficient modules over $K[w]$,

$$(a(w), b(w)) \mapsto (a(w), w b(w)), \quad (a(w), b(w)) \mapsto b(0) \quad (\text{CC-S S7})$$

is an injective map followed by a surjective map, with the image of the first equal to the kernel of the second. The proof divides every zero-constant-coefficient polynomial by w . `SplitZeroSpecializationChart.lean` constructs these linear maps and proves all three assertions.

After specialization at $w = 0$, the two-term map is $\text{diag}(1, 0)$, not an injective map. Its kernel is the full modified summand E_1 , and second projection identifies its cokernel with E_1 . Globally, the degree-minus-one fibre is $E_1 \otimes \mathcal{O}(-1)|_\infty$; choosing the local generator in (S7) trivializes that line, but does not erase its transition factor. The local Lean statements prove the kernel/image calculations; they do not construct the derived category of coherent sheaves or an Ext duality functor.

The actual source map on this chart is

$$\Psi_\infty(w) = R_j P_0 + w R_j P_1 + \delta R P_1, \quad B_j \Psi_\infty(w) = P_0 + w P_1. \quad (\text{CC-S S8})$$

It is injective. For $w \neq 0$, apply the observation and the invertibility of (S6). At $w = 0$, a relation $R_j x_0 + \delta R x_1 = 0$ first gives $x_0 = 0$ under B_j , then $x_1 = 0$ because $\delta R|_{E_1}$ is injective. The induced metric on (S5) is thus smooth and positive at infinity even though the quotient comparison has the exceptional fibre above.

S41.1.3 3. The action pole and the least invariant repair

On the overlap, every action block is retained:

$$\alpha(w)^{-1} A \alpha(w) = P_0 A P_0 + w P_0 A P_1 + w^{-1} P_1 A P_0 + P_1 A P_1. \quad (\text{CC-S S9})$$

The polar coefficient vanishes exactly when $A E_0 \subseteq E_0$. This is not assumed. The formal chart theorem proves (S9) and its invariance criterion.

The least action-invariant subspace containing E_0 is

$$F_A = \text{span}\{A^n v : n \geq 0, v \in E_0\}. \quad (\text{CC-S S10})$$

`SplitZeroActionHull.lean` constructs (S10) as a submodule and proves containment, invariance, its universal minimality, monotonicity, idempotence, and the criterion $F_A = E_0$ iff E_0 is invariant. These assertions do not require finite dimension.

When $\dim E = q$, Cayley–Hamilton expresses A^q as a linear combination of the preceding powers. Multiplying this relation by further powers and inducting gives

$$F_A = E_0 + A E_0 + \cdots + A^{q-1} E_0. \quad (\text{CC-S S11})$$

This finite truncation is a written consequence, not an additional claimed Lean target in this package.

Compute the repair directly in the original cyclic quotient Let $p_1, \dots, p_m$ be the polynomial representatives of any basis of E_0 , retaining all multiplicities in χ . Define the monic polynomial

$$d = \gcd(\chi, p_1, \dots, p_m). \quad (\text{CC-S S12})$$

The full inverse image of F_A under $\mathbb{C}[S] \rightarrow E$ is the ideal generated by $\chi, p_1, \dots, p_m$. Indeed invariance under $A = M_S$ is precisely closure under polynomial multiplication. The principal ideal theorem in $\mathbb{C}[S]$ identifies this ideal with (d) . Therefore

$$\boxed{F_A = (d)/(\chi), \quad E/F_A \cong \mathbb{C}[S]/(d).} \quad (\text{CC-S S13})$$

Multiplication by d gives the additional module isomorphism

$$\mathbb{C}[S]/(\chi/d) \xrightarrow{\sim} F_A. \quad (\text{CC-S S14})$$

Surjectivity is immediate from the ideal description. If $df \in (\chi) = (d(\chi/d))$, cancellation in the polynomial domain gives $f \in (\chi/d)$, proving injectivity. The formula also handles $E_0 = 0$, where $d = \chi$, and $d = 1$, where the repair is all of E .

In particular, with $s_A = \dim F_A - \dim E_0$,

$$\boxed{s_A = r - \deg d, \quad \dim(E/F_A) = \deg d.} \quad (\text{CC-S S15})$$

This computes which arithmetic constituents remain at the boundary of the action-stable repair. It does not identify that boundary with the full original quotient.

S41.1.4 4. The repair's metric pole has a signed curvature contribution

The repaired lattice is the preimage of F_A under specialization of $E \otimes \mathcal{O}$ at infinity. It contains $\mathcal{M}$, with torsion quotient of length s_A . In compatible local frames the inclusion determinant vanishes to exactly order s_A . Hence the metric transported from the same source satisfies

$$\det G_A(w) = |w|^{-2s_A} \det G_{\mathcal{M}}(w). \quad (\text{CC-S S16})$$

The determinant metric was not replaced by a newly selected smooth metric on the larger lattice. With $dd^c = (i/2\pi)\partial\bar{\partial}$, the dual determinant's curvature current is

$$\boxed{\mu_A = \mu_{\mathcal{M}} - s_A \delta_{\infty}.} \quad (\text{CC-S S17})$$

To verify the sign, take logarithms in (S16) and use $dd^c \log |w|^2 = \delta_0$. The latter normalization follows from Green's identity on a punctured disk: its shrinking boundary integral is the test function's value at the origin. The smooth part is unchanged off infinity, and the polar logarithm contributes a negative atom to the dual determinant curvature.

The total degree is correspondingly

$$\deg \det(\mathcal{M}_A)^\vee = r - s_A = \deg d. \quad (\text{CC-S S18})$$

Thus an action-stable repair can have degree zero while retaining a nonzero positive curvature density on the affine chart, compensated by a negative atom at infinity. Degree zero does not force the original curvature cost to vanish. This is an exact account of the metric pole, not a counterexample to an unproved arithmetic estimate.

For the declared Gaussian polynomial fixture $\psi(u) = u^3 + u$, $(i, j) = (2, 5)$, the retained zero mode generates the whole cyclic module: its polynomial is coprime to ψ . Then $r = s_A = 2$ and $d = 1$. The initial curvature has degree two, while the repaired current has a negative atom of mass two and total degree zero. This fixture uses the monic Hermite norms with mass seven and the literal phase i^n ; it is not asserted to be an arithmetic zero packet.

S41.1.5 5. Curvature and the existing restriction certificate are the same cost

Let $K_i = G_i^{-1}$, $K_j = G_j^{-1}$, and retain the two distinct operators

$$Z = K_j(G_i - G_j) = (K_j - K_i)G_i, \quad T = K_i G_j, \quad H = 1 - T. \quad (\text{CC-S S19})$$

The original inverse equations give

$$(1 + Z)T = T(1 + Z) = 1, \quad H = Z(1 + Z)^{-1}. \quad (\text{CC-S S20})$$

These identities are formalized directly, without imposing Euclidean Hermitian symmetry on either operator. The cost spectrum of Z is nonnegative because Z is similar, via the original positive Gram matrix, to $G_j^{-1/2} C G_j^{-1/2}$. If $\lambda \geq 0$ is a cost eigenvalue, its return-loss coordinate is

$$x = \lambda/(1 + \lambda) \in [0, 1). \quad (\text{CC-S S21})$$

Every zero mode remains in this finite spectrum. For $t = |z|^2$, radial determinant curvature and cumulative mass are

$$\kappa(t) = \sum_a \frac{\lambda_a}{(1 + t\lambda_a)^2}, \quad M(t) = \sum_a \frac{t\lambda_a}{1 + t\lambda_a}, \quad M'(t) = \kappa(t). \quad (\text{CC-S S22})$$

The scalar derivative and its first derivative are checked in Lean. Changing to the bounded spectrum gives

$$\kappa(t) = \sum_a \frac{x_a(1-x_a)}{[1-(1-t)x_a]^2}. \quad (\text{CC-S S23})$$

The original logarithmic moment is

$$\mathcal{L} = \int_0^1 \log(1/t) \kappa(t) dt = \sum_a \log(1+\lambda_a) = \sum_a -\log(1-x_a). \quad (\text{CC-S S24})$$

For completeness, integrate by parts using (S22). At zero the boundary term $M(t) \log(1/t)$ vanishes since $M(t) = O(t)$ for each fixed finite block; it also vanishes at one. The remaining integral is $\sum_a \int_0^1 \lambda_a / (1+t\lambda_a) dt$, giving (S24). This integral argument is written analysis; the equality between the two finite logarithmic sums is formalized.

Write $s_m = \text{Tr}(H^m) = \sum_a x_a^m$. At $t = 1$,

$$M(1) = s_1, \quad \kappa(1) = s_1 - s_2. \quad (\text{CC-S S25})$$

More generally the rational normalized coefficients are

$$b_n = \sum_a \frac{\lambda_a^{n+1}}{(1+\lambda_a)^{n+2}} = s_{n+1} - s_{n+2}. \quad (\text{CC-S S26})$$

Direct repeated differentiation gives $b_n = (-1)^n \kappa^{(n)}(1)/(n+1)!$. The all-order differentiation interpretation is written, whereas (S26) itself and its telescoping consequence are formalized:

$$s_{p+1} = M(1) - \sum_{n=0}^{p-1} b_n. \quad (\text{CC-S S27})$$

Thus the curvature data feed the already verified trace-only certificate. Put $P_p = \sum_{m=1}^p s_m/m$. Once $s_p < 1$,

$$P_p \leq \mathcal{L} \leq P_p + \frac{P_{2p} - P_p}{1 - s_p}. \quad (\text{CC-S S28})$$

The upper formula is evaluated on actual complex matrix traces via the previously formalized spectral witness, not by pretending that the original H is Euclidean Hermitian. Every fixed finite block has some successful stopping degree, since $s_p \rightarrow 0$. This is not a uniform stopping-degree or arithmetic upper-growth theorem as the packet grows.

S41.1.6 6. Integration with the new source

The normalized Hochschild trace comparison $\mathcal{U}$ in HOCHSCHILD_COMPARISON.md is isometric on the original half-line source. Applying it to (S3) therefore leaves (S19)–(S28) unchanged. Its arithmetic Laplacian is $A^2 - kA$, not the metric loss H . The exact connection is through $W = A^*G + GA - kG$, whose Laplacian adjoint defect is $A^*W - WA$. The two spectra have different meanings and have not been identified.

The original supported lifts of all coefficient maps are retained. The ordinary local chart $w = 0$, an amplitude killed by critical-line observation, and the structural absence scalar τ are three different data. None is substituted for another.

S41.1.7 Verification boundary

The workflow compiles five new Lean modules individually at `--trust=0` with warnings as errors. Its selected new transitive audits have 29 specialization/curvature declarations and nine Laplacian/intertwiner declarations. It also replays the inherited restriction declarations and regressions. Actual status is recorded in STATUS.md after observing the run; this note is not itself a compiler certificate.

The general source construction, coherent-sheaf globalizations, metric current (S17), cyclic gcd description (S13), all-order derivative formula, and integral (S24) have written proofs above. They are not silently included in the Lean scope. The original source note's 23-method archive was not re-executed in the unavailable local runtime; the new repository's 17-method exact checker is a separate suite, and the companion Laplacian checker has ten methods.

The publication sources in main 1f7e7c02343884a17df9873566e81a9083c70951 and every PR26 addition at e382e4f61aa4a61b621a8f064dfefc1ab80640d8 remain intact on the integration branch. No frozen reader, dependency pin, inherited mathematical source, or main branch is changed by this work.
